IN the June number of the *Chronica Medica Mexicana* Dr. Juan Duque de Estrada describes what he believes to be a previously unrecorded variety of contracted pelvis. The patient, a Mexican girl, sixteen years old, was delivered with great difficulty by perforation of the aftercoming head, the child having presented by the breech and the head being completely arrested above the brim of the pelvis. On examination the pelvis presents two striking peculiarities—complete ankylosis of the left sacro-iliac articulation and of the symphysis pubis. The bones of the pelvis as a whole are mal-developed and all the diameters except the antero-posterior of the outlet are markedly diminished. The left iliac fossa is smaller than the right and the left ilium is completely ankylosed to the atrophied left wing of the sacrum. The left ilio-pectineal line is too curved posteriorly, while anteriorly it is too straight and with the whole of the left wall of the pelvis appears to be pushed over to the right by the pressure of the left femur. The two halves of the pubes are completely ankylosed, only a slight trace of the line of the joint being visible upon the anterior surface. The symphysis pubis is directed forward in a keel-like manner and deviates to the right of the middle line. The right sacro-iliac articulation and the right iliac fossa are normal. The right ilio-pectineal line posteriorly is less curved than normal and anteriorly resembles the left in being almost straight. The asymmetry of the sacrum is very striking, the left half, markedly atrophied, is less than half the size of the right half. The whole bone appears to be rotated about both a vertical and an antero-posterior axis, so that the anterior surface looks to the left while the upper surface of the atrophied left wing is some millimetres higher than the upper surface of the right wing. The result of the abnormal curvature of the two ilio-pectineal lines and the flattening of their anterior extremities, together with the deviation of the anterior surface of the sacrum, is to give the inlet of the pelvis an obliquely triangular form. The left pelvic wall is pushed in towards the middle line, so that the left ischial spine and the left ischial tuberosity project inward to a greater extent than normal. The same condition, though less marked, is present upon the right side, so that the transverse diameters of both the cavity and the outlet of the pelvis are diminished. The subpubic arch forms an angle of 52°. The sacrum is not only rotated upon a vertical and antero-posterior axis, but also upon a transverse axis, so that the antero-posterior diameter of the outlet is increased by the deviation backwards of the lower end of the sacrum and coccyx. The pelvis resembles a Naegelé oblique pelvis in the ankylosis of the left sacro-iliac joint, the atrophy of the left wing of the sacrum, the deviation of the sacrum to the affected side and of the symphysis pubis to the sound side, the flattening of the left pelvic wall and the inward projection of the left ischial spine and the left ischial tuberosity. The same conditions, however, though to a less extent, exist upon the opposite side: thus there are some want of development in the sacrum, some flattening of the pelvic wall and some undue prominence of the ischial spine and ischial tuberosity, and these facts show that the diminution in the diameters is not due to a change affecting one side of the pelvis alone but to changes affecting both sides. While in many of its characters the pelvis undoubtedly resembles that of Naegelé it differs from it in the projecting keel-like form of the symphysis pubis, in the slight separation of the two ischial tuberosities and the consequent shortening of the transverse diameters, and in the smallness of the subpubic angle. In these it approaches the type of the transversely contracted pelvis of Robert. Dr. Juan Duque de Estrada thinks that the latter characters are sufficiently marked to show that it is not merely a Naegelé oblique pelvis modified by the ankylosis of the symphysis pubis, but that it represents a type of pelvis midway between that of Naegelé and that of Robert, for which he proposes the name of the "Mexican pelvis." The occurrence of bony ankylosis between the two halves of the pubes is an exceedingly rare event, and even in those cases where from the difficulty experienced in dividing the joint in the operation of symphysiotomy it has been diagnosed as present it is a little doubtful whether the difficulty was not due rather to deviation of the line of the joint than to bony ankylosis.

LUMINOUS SUGAR.

THERE are phenomena attending the formation of crystals which are apparently quite distinct from chemical action. When, for example, a hot saturated solution of arsenious acid is allowed to cool the act of crystallisation is accompanied by a flash of light. As each crystal forms there is a short sharp glow indicating the release of a certain amount of latent energy in the form of light radiation. A related phenomenon would seem to be the case when two pieces of cane sugar are quickly rubbed together. The flash is perfectly distinct and bluish-white in colour, the light extending into the substance itself far below the surface. Some interesting experiments on this manifestation have recently been made by Mr. John Burke, M.A., the results of which were communicated to the recent meeting of the British Association

Digitized by Google

of Science at Bristol. By mounting discs of loaf sugar on a lathe and projecting a hammer on the rotating surface an almost continuous luminosity was obtained. The wearing away of the sugar is compensated for by arranging a gradual approach of the piece to the hammer in exact accordance with the amount of sugar scraped away. In this way the spectrum has been observed and photographed. From these observations it would appear that the luminosity cannot be due to the particles of sugar becoming red hot or white hot by the impacts, the indication being that the light produced is due either to some change in the configuration of the crystals of sugar or to some sort of chemical action set up between the sugar and the surrounding air at the freshly formed surface. The fact, however, that the surrounding medium does not seem to affect either the colour or intensity of the luminosity suggests that the effect is not due to any influence of a chemical nature of the surrounding medium on the sugar, but favours the former hypothesis that the luminosity is due to some structural disturbance in the sugar itself. This ingenious and pretty study is being pursued further and the results should lead to some interesting observations. Light is so often a manifestation of physical change that it is probable some day we shall derive it for illuminating purposes in a totally different, much simpler, and less clumsy way than obtains at present.

EGYPTIAN VITAL STATISTICS.

DR. ENGEL BEY, the head of the statistical branch of the Egyptian Sanitary Department, has published the second part of a *résumé* of his weekly bulletins for the quinquennial period 1886–90. The first part, which appeared in 1895, was devoted exclusively to climate, but in his present work he deals mainly with births and deaths, his purview, however, being limited to nineteen of the principal towns of Lower Egypt. Vital statistics in Egypt may be said to be still in their infancy, having been born, so to speak, in 1886, when Dr. Engel first undertook the onerous task which he has so strenuously endeavoured to carry on in the face of countless more or less unavoidable difficulties. It is true that in the time of Clot Bey a system of registration was introduced which in theory was admirably comprehensive, but practically the results could never be depended on owing to the ignorance and corruption of the native officials and also to the absence of a trustworthy census. The latter defect was remedied last year, and now that the Soudan question has been so triumphantly resolved it is to be hoped that funds may be forthcoming to establish the vital statistics of the entire country on an assured basis.

A NOTIFICATION ANOMALY.

FEW provisions of the Public Health Acts afford a better illustration of the oversight of Parliamentary criticism than is presented by that portion of Section 55 (1) (*b*) of the Public Health (London) Act, 1891, which enacts that "when the certificate refers to the inmate of a hospital it shall specify the place from which and the date at which the inmate was brought to the hospital, and shall be sent to the medical officer of health of the district in which the said place is situate." Now, the effect of this provision as to the destination of the certificate is that, although the patient may have been in the hospital in question for even six months or more, when the notifiable condition develops, the medical officer of health of the district in which the hospital is situated must remain in ignorance of the case while the medical officer of health of the place from which the subject was brought, perhaps a year previously, receives the certificate. In other words, if an outbreak of typhus fever occurred in a London hospital amongst patients brought from a distance, the medical officer of health of the district containing the hospital might, in so far as legal obligations go, be unaware of the occurrence. The remedy for this state of affairs is obviously simple, and consists in having a certificate forwarded to each of the medical officers of health who might be concerned, or by leaving it open to the notifying medical man to send the certificate to whichever source he regards the evidence as indicating. Or, again, a certain limit of time might be fixed—say a month—during which a certificate should be dispatched to each district concerned, whereas after the lapse of that interval all certificates should go to the medical officer of health of the district in which the hospital is situated.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THIS society has secured considerably extended accommodation for its members in the new wing of the West London Hospital through the kindness of the authorities. Its membership of over 500 produced such a large attendance during the last year that the board-room of the hospital was wholly inadequate. The first meeting of the winter session 1898–99 will be held on Friday, Oct. 7th, at 8.30 P.M., when the President, Dr. S. D. Clippingdale, will deliver his opening address on "Some Considerations of the Life and Work of a General Practitioner."

THE PLAGUE IN INDIA.

THE plague seems to be widely spread in India, and the latest accounts from Bombay show an increase in the total mortality in that city for the week ending Sept. 10th, as well as a slightly increased death-rate from plague over that of the previous week. It has been felt that no system of quarantine and severely restrictive measures for the repression of plague could be carried on for years without inflicting grave hardship on the population and bringing about disastrous commercial consequences. The Government have therefore decided to make certain changes in the regulations with reference to railway travelling. Detention camps and passes will be discontinued, and a strict medical examination accompanied by disinfection of clothing will be instituted at convenient centres and at places of arrival. Persons coming from infected localities will be subject to surveillance for ten days after arrival. Further details from our Special Correspondent will be found in another column

THE USE OF TOXINS IN INOPERABLE SARCOMA.

DR. WILLIAM B. COLEY, of New York, has lately read a paper before the American Medical Association in Denver on the Treatment of Inoperable Sarcoma with the mixed toxins of Erysipelas and Bacillus Prodigiosus, with the immediate and final results in 140 cases. An abstract of the paper is given in the *Medical Record* of New York of August 27th and is worthy the attention of surgeons. He says: "No one could possibly witness a number of hopelessly far advanced inoperable sarcomata, the diagnosis of which had been confirmed by the most skilled pathologists, entirely disappear under injection of these toxins without being convinced that there is something of value in them. The successful cases which have now remained well beyond three years more than offset the many failures." He does not recommend the treatment in cases amenable to operation "unless it be in a few cases in which a brief period of treatment was advised with the idea of avoiding amputation of a limb." He thinks it advisable to try to save a limb if the tumour be in the soft parts and especially if spindle-celled. He gives a case which excites hope and justifies the treatment—that of a patient, now well for nearly two and a

Digitized by Google

half years, with rapidly recurrent spindle-celled sarcoma of the right hand in which amputation would have been performed had not the growth disappeared under the injections. He gives the following summary of results: "Well over three years, 8 cases; well from one to three years, 9 cases; well from six months to one year, 4 cases; recovered after having once disappeared, 4 cases; 2 of these patients died, 2 are still living in good health after further treatment." He has collected from published reports and personal communications from other surgeons 35 cases of inoperable sarcoma in which the tumour completely or very nearly disappeared as a result of this treatment. The chief dangers of it are too large a dose of the toxins and pyæmia from insufficient precautions as regards asepsis.

THE GUILD OF ST. BARNABAS.

THE objects of the above guild are the encouragement of a high ideal of faith and practice amongst students of medicine who are members of the Church of England. The guild services are open to all medical students. Further information may be had on application to the honorary secretary, Mr. B. E. G. Bailey, 14, Woburn-square, W.C. We are asked to give publicity to the following. There are monthly guild services in the North-West Chapel, St. Paul's Cathedral (entrance by west door), at 6.15 P.M. on the first Wednesday of every month—namely, on Oct. 5th, Nov. 2nd, and Dec. 7th. Tea in the Chapter House (north side of Cathedral) at 5.45 P.M. Sessional Corporate Communion in the Jesus Chapel, St. Paul's Cathedral (entrance by small south-east door), at 7.30 A.M. on Thursday, Oct. 6th. The chaplain of the guild is the Rev. Canon Newbolt.

COMBINATION HOSPITALS FOR INFECTIOUS DISEASES.

ALTHOUGH sanitary authorities, such as urban and rural district councils, may combine together under the Isolation Hospitals Act of 1893 very few authorities have availed themselves of the opportunity. When a number of authorities do so it is gratifying to record such a step which is in the direction of progress in the prevention of infectious disease. Chorley Corporation and Chorley Rural District Council, at the suggestion of Dr. Harris, medical officer of health of both bodies, have combined with Adlington and Leyland District Councils to build a joint hospital for infectious diseases, and the foundation-stone was laid recently at Heath Charnock, Lancashire. The hospital will be under the control of the Chorley Joint Hospital Board which will consist of representatives of the four authorities mentioned. The plan of the hospital is on the pavilion system, three of the pavilions being for the accommodation of patients; besides these there will be one block for administrative purposes and another for laundry, electric lighting supply, disinfecting rooms, harness and van rooms, &c. The blocks will be 50 ft. apart. The infectious diseases provided for are diphtheria, scarlet fever, and enteric fever. The diphtheria block will contain 4 wards, 8 beds, and 2 nurses' rooms; the scarlet fever pavilion will have 2 wards, 16 beds, and a nurse's room; and the enteric fever block will comprise 2 wards, 12 beds, and a nurse's room—a total of 36 beds and 4 nurses' rooms. The contract for the building is £10,000, the total cost of the whole buildings to be erected being £17,000. This joint hospital is to make provision for a population of 50,240, according to the last census in 1891, a total acreage of 48,445 acres and a rateable value of £272,559. 24 townships are to participate in the benefits of this hospital. We congratulate Dr. Harris, the medical officer of health of Chorley and Chorley Rural District Council, upon his perseverance in recommending the authorities to combine and provide a suitable hospital for infectious cases. His recommendations were first made in 1892, and now, six years after, he has the pleasure of seeing a commencement of the necessary work. We regret, however, that the accommodation is not greater, but probably this can be easily remedied afterwards. 16 beds for scarlet fever and 12 for enteric fever in a population of over 50,000 is not sufficient; 1 bed per 1000 has been found to be quite little enough for isolation purposes, but no doubt these pavilions will be built so as to admit of their enlargement in the future. We trust that other district councils will follow this example.

THE HEALTH OF THE PRINCE OF WALES.

IN the letter from our Paris correspondent which we publish this week will be found some criticism from the pen of Dr. Lucas Championnière with regard to the treatment of the Prince of Wales's fractured patella. We need not comment on this criticism, but are glad to be able to say, on the authority of Sir William MacCormac, who has just returned from visiting His Royal Highness at Mar Lodge, Braemar, that His Royal Highness is progressing most favourably both as regards his general health and the local injury.

LONDON POST-GRADUATE COURSE.

THE winter term of the above course will commence on Monday, Oct. 10th. Courses of lectures and demonstrations will be given on Skin Diseases (Hospital for Diseases of the Skin, Stamford-street, Blackfriars), on Mental Diseases (Bethlem), on Diseases of the Throat, Nose, and Ear (London Throat Hospital), on Bacteriology (King's College), on Public Health (Parkes Museum), and on General Medicine and Surgery (Cleveland-street). All the classes can be taken out or a portion of them. The fees are from £1 1*s.* to £3 3*s.* It is hoped that the work of the course will be merged in that of the Medical Graduates' College, which it is expected will be opened early in the new year. Particulars can be obtained from, and fees paid to, the secretary, Dr. Fletcher Little, 32, Harley-street, W.

PTOMAINE POISONING.

AT this period of the year symptoms of ptomaine poisoning after the consumption of decomposing meat are by no means infrequent and we have more than once drawn attention to the uncertainty with which meat containing these poisons can be detected, and also to the fact that if several people eat portions of the same joint some may be seriously affected while others escape completely. On Sept. 16th Mr. Walter Schröder, the deputy coroner for Mid-Surrey, concluded an inquiry concerning the deaths of two people, a cook and a nurse employed in the same household. The women died on August 23rd and 27th respectively from the effects of ptomaine poisoning. A local butcher had supplied to the family a tongue and some lamb. All the members of the household, including a visitor, were in good health until August 19th. On the morning of that day the lamb was cooked for lunch and partaken of by eight people. Later in the day all were taken ill and two of the cases proved fatal. After the sickness had occurred the tongue, which had been purchased on the 10th, was found to be "putrid and maggoty." The lamb, before being cooked, had been put in the same larder but not in close proximity to the tongue. After hearing evidence the jury found "that the deceased died from exhaustion and gastro-enteritis consequent upon ptomaine poisoning due to a joint of lamb eaten by them on August 19th, that the contagion was due to the presence of a portion of an ox-tongue in the larder in a putrid state, and that the said deaths were the result of misadventure, nobody being to blame." 4 gr. to 5 gr. of a ptomaine were

Digitized by Google

found in the viscera of the deceased and the analyst expressed the opinion that the lamb had become contaminated through being put in the larder with the tongue and it was highly probable that the contagion was conveyed from one to the other by flies. This suggests a startling possibility and may throw considerable light on the exceedingly toxic character of meat which otherwise to taste and smell and by other evidence appears perfectly wholesome. Flies should always be rigorously kept out of the larder and meat stores because there is never any certainty as to the character of the last place of their alightment. The adoption of gauze safes and covers is therefore a wise precaution.

ANNUAL DINNERS OF THE MEDICAL SCHOOLS.

IN addition to the list we have already published—see THE LANCET of Sept. 10th, p. 706—we wish to announce that the annual dinner of the St. George's Hospital Medical School will be held to-day (Saturday, Oct. 1st) at the Whitehall Rooms of the Hôtel Métropole at 7 30 P.M., under the chairmanship of Mr. Timothy Holmes, Treasurer of, and Consulting Surgeon to, the Hospital; that of King's College Hospital Medical School at Limmer's Hotel on Monday, Oct. 3rd, at 6.30 for 7 P.M., Mr. Boyce Barrow in the chair; and that of Westminster Hospital Medical School also on Oct. 3rd, at the Holborn Restaurant, at 7.30 P.M., Sir G. S. Robertson, K.C.S.I., in the chair.

THE SIXTH INTERNATIONAL OTOLOGICAL CONGRESS.

THE Sixth International Otological Congress will be held in London on August 8th, 9th, 10th, 11th, and 12th, 1899. President, Dr. Urban Pritchard, Professor of Otology at King's College, London. The meetings will, by permission, be held at the Examination Hall of the Royal Colleges of Physicians and Surgeons, Victoria Embankment. The subject chosen for special discussion is "Indications for Opening the Mastoid in Chronic Suppurative Otitis Media." A large and influential British organisation committee has been formed, the treasurer being Mr. A. E. Cumberbatch, 80, Portland-place, London, W., and the honorary secretary, Mr. Cresswell Baber, 46, Brunswick-square, Brighton. The International Otological Congress, which assembles every four years, met last in Florence, where a very successful gathering was held under the Presidency of Professor Grazzi.

A NEW SYSTEM OF NOTIFICATION OF MEASLES.

WHAT may be called the orthodox notification of measles is being pursued in sundry sanitary districts with varying degrees of perseverance and with varying results. Those who do nothing but sit still and gaze at the certificates as they arrive, and who grumble periodically as often as the notification bill becomes due are naturally somewhat uncertain as to the value of notification. So, too, are those who adopt the notification of measles but who at the appearance of the first account strike off the disease from the list. Again, those who are endeavouring to deal in some degree with the notified cases are somewhat divided in their opinions. Here they are satisfied as to the value of the proceedings; there they are hesitating. In the borough of St. Helens the notification of measles is partial and what must be termed unorthodox. But in spite of both these facts we shall watch the system with interest. The head teachers of the several schools in the borough are supplied with properly prepared postcards addressed to the medical officer of health, Dr. Drew Harris. On these cards the teachers are requested to notify any suspected cases of measles which may come to their notice. If the suspected case turns out to be measles the teacher receives the sum of 3*d.* for his or her trouble, and as an illustration of the hopeful character of this new system it may be related that out of 988 suspicious cases which were recently reported 582 proved to be cases of measles. Each case was visited by the female sanitary inspector, the necessary particulars were procured, and advice was given; all children from infected houses were excluded from school attendance. There can be no doubt, Dr. Harris reports, that by this means many lives were saved and that the epidemic which prevailed was materially curtailed. The cost of the system was not great.

PAPILLOMATA OF THE URETHRA.

IN the *Boston Medical and Surgical Journal* of July 7th Dr. F. G. Balch has published a case of this rare form of urethral disease. Tumours of the urethra are comparatively infrequent. Papillomata, polypi, and carcinomata occur. Of these papillomata are the most common. According to Klotz they occur frequently in or near the meatus, but are much less common farther down. Papillomata are usually multiple, bleed easily, and are sometimes tender. A young man, aged twenty years, had a mild gonorrhœa, and four years afterwards had sounds passed for seminal emissions. He noticed a wart growing from the edge of the meatus and a slight purulent discharge from the urethra. He had not been exposed to venereal infection. The wart was cauterised with chromic acid but returned. There was considerable obstruction to the flow of urine, which came in a small scattered stream. The meatus was divided, and by means of the endoscope the anterior urethra was found to be thickly studded with papillary growths, the deepest being 2 in. from the meatus. They varied in size from that of a pin's head to that of a cherry-stone. Under cocaine they were removed with a curette. There was some trouble in scraping away the bases which were very firm. The raw surface was touched with glacial acetic acid. A week later the anterior urethra was painted with a solution of nitrate of silver (10 grains to the ounce). After two weeks two or three minute growths appeared near the meatus and were touched with glacial acetic acid. The result was completely successful.

AN AMERICAN VIEW OF THE VACCINATION ACT, 1898.

OUR contemporary the *New York Medical Record* is evidently much shocked with the new principle introduced into our vaccination laws by Section II. of the Vaccination Act, 1898, as gradually abolishing the compulsory principle. The editor says: "If false beliefs conscientiously held are to be allowed to stand in the way of the safety of the community there is an end of all sanitary legislation. A person who is allowed to refuse vaccination on conscientious grounds may refuse to isolate a patient with small-pox and the State cannot consistently force him to do so. And this in the country of Jenner!" In a later number (Sept. 10th) the editor returns to this subject and says that "by far the most important event which has occurred in the English medical world within the memory of the present generation has recently been consummated. The Compulsory Vaccination Bill has been practically rendered of no effect in England." The writer contrasts this action with the sentiment of the United States and with the universal faith in vaccination in the leading countries of Europe. "All countries of the civilised world," our contemporary says, "will watch with interest the tremendous experiment." In spite of the law, however, the "tremendous experiment" will have its limitation, for it is found that the medical officers of health of the most rabidly anti-vaccinationist communities are quite sound on the vaccination question.

Digitized by Google

They have extra early intimations of actual cases and vaccination and revaccination and severe isolation are immediately set in motion. The most conscientious objector revises his faith and takes the benefit of the doubt, and only hundreds die where, if he had his way and retained his faith, thousands would succumb. Thus the most guilty communities are saved by medical men and the laws which they have promoted, including that of vaccination.

UMBILICAL ERYTHEMA.

A SHORT paper by Dr. P. Bar is quoted in the *Journal de Clinique et de Thérapeutique Infantiles* of Sept. 15th, 1898, in which the writer directs attention to the not infrequent occurrence of umbilical erythema, sometimes attended by septic absorption, in newly-born children. He believes that this condition is due in many cases to septic infection induced or encouraged by the practice of bathing infants during the first days of life. More especially is this cause accountable in some maternity hospitals where one bath is used for a succession of children and is not always properly cleansed. Such at least is his experience. On the other hand, he has had highly satisfactory results by adopting the following method. The segment of umbilical cord left attached to the child after ligature is at once wrapped in cotton-wool and bound in the usual way. No water is used. The skin is cleaned of its caseous coating by means of a cotton-wool swab soaked in an alcoholic solution—eau de cologne, for example. After two days the segment of the cord has practically withered and, with the exception of a small portion next the umbilicus, is cut away, the stump being dressed with iodoform gauze and absorbent wool. No bathing is done till after the cicatrisation of the umbilicus on or about the fifth day, save that the hips and groins are cleansed with boiled water when needful. After this date the child is bathed as usual. This method is avowedly intended more for hospital than for private practice for the reason stated above. Practitioners in this country may, perhaps, consider that Dr. Bar's abhorrence of the bath is excessive, and they will probably prefer to entrust even the dried umbilical segment to the natural efforts for separation. They are certain also, however, to appreciate the principle of a dry and aseptic umbilicus which underlies his observations, a principle which is still apt to be forgotten in the practice of midwifery nurses.

THE annual medical service of the Guild of St. Luke will be held in St. Paul's Cathedral on Wednesday, Oct. 19th, at 7.30 P.M., when the Bishop of London will preach the sermon. All practitioners who are graduates are requested to wear hood and gown whether they have a medical degree or otherwise, and Fellows of the Royal College of Surgeons of England are requested to wear their Fellows gowns.

ACCIDENTS TO MEDICAL MEN.—On Sept. 23rd, at the South-Western Railway Station at Salisbury, an engine dashed into a carriage in which were members of the Teign Naturalists' Field Club who had been on a visit to Salisbury, conducted by Mr. C. H. Wade, L.R.C.P. Lond., M.R.C.S. Eng., vice-president of the association. The party included five medical men, Dr. F. C. H. Piggott (of Teignmouth), Mr. C. H. Wade (Torquay), Dr. Brushfield (Budleigh-Salterton), Mr. Skardon (Paignton), and Mr. P. Q. Karkeek, the medical officer of health of Torquay. Mr. Skardon received injuries to his head and Mr. Karkeek suffered from shock and contusion of the neck and shoulders.—On Sept. 20th Mr. Joseph Harper, L.R.C.P. Lond., M.R.C.S. Eng., J.P., of Barnstaple, was badly bruised in a carriage accident. Mrs. Harper, who accompanied him, was severely injured and is suffering from cerebral concussion.]

PROFESSOR KOCH ON TROPICAL MALARIA.

ONE of the most interesting of his "Reise-Berichte," noticed in THE LANCET of Sept. 24th, p. 825, is the report sent by Professor Koch from Daressalam, German East Africa, on Feb. 25th of the present year. It is devoted to the subject of malaria, which he points out is the common endemic of the country, where typhoid fever and diphtheria are almost unknown and even dysentery occurs but rarely, at least on the coast. But from 1891 to 1896, in the Daressalam Hospital of 899 patients, 485, or 54 per cent., were cases of malaria. The variety is that known as tropical malaria, causing anæmia and weakness with great tendency to recurrence, not seldom appearing in a fatal pernicious form, as the so-called "blackwater fever." Professor Koch, in investigating the affection, selected only those cases which clinically ran the characteristic course and were influenced by quinine. In all such he found the malaria parasite in the blood, whilst he never succeeded in detecting this in other cases regarded as malarious but not possessing the characteristic clinical features. Thus of 154 cases examined 72 were true malaria and exhibited the parasite, 63 of them being tropical malaria, 7 were tertian, 1 quartan, and 1 "irregular" malaria. He came to the conclusion that blackwater fever could not be regarded as truly malarious and proposed to make a special report on that affection. The solitary examples of quartan and irregular fever were, he thought, imported cases, whilst the proportion of tertian to tropical forms—7 to 63—showed that the type which is most common in Europe is least so in East Africa. Tropical malaria is, he says, distinguished from other forms by its peculiar course and the particular kinds of blood-parasites which are regularly found in it. As most of the cases in hospital were already under treatment by quinine when he examined them it was not easy to obtain a correct notion of the natural course of the disease, and it was not until he had the opportunity of seeing cases at a sufficiently long interval after quinine had been suspended that such a view of the characteristic type of tropical malaria could be gained. He was then surprised to find the paroxysms approximating to the tertian type, but differing from European malaria in the long duration of each individual attack, the fever lasting over two days and remitting more or less markedly on the morning of the second day. The temperature curve thus comes to have a superficial resemblance to quotidian, especially when the remission on the second day is strongly marked, but a true quotidian was not observed, and he thinks it likely that such rarely, if ever, occurs in East Africa. It is singular that the onset of the fever is almost invariably at midday or in the evening, whilst the apyrexial period regularly commences in the forenoon. The course of development of the parasite accords with the type of the temperature curve. It has the characters described by other observers in the quotidian malaria of other tropical countries, assuming the signet ring form, and it increases in size, a point not hitherto noticed but of importance in determining the nature of the attack. The smallest size of the ring-shaped parasite is from one-eighth to one-sixth the diameter of a red blood corpuscle, and when it attains its largest size its diameter is about one-half that of the corpuscle it inhabits. The smallest (and youngest forms) present only a single nodular thickening at one part of the delicate ring, which stains deeply and appears as a dark spot on the circumference of the circle. As the sphere enlarges its border becomes thickened along a certain distance, and always at the opposite pole to the site of the nodule or nodules. This thickening increases until a portion of the sphere has the shape of a sickle and vacuoles appear in the thickened part. The parasites of tertian and quartan fever contain pigment in amount corresponding to the size and age of the parasite, but in tropical malaria the parasite is colourless, or rather its pigment is concealed, occurring in such fine granules that it is only in the most advanced stages and by most careful inspection that it can be detected as a brownish tint in the thickened area. That they do contain pigment is further evident from the examination of the spleen in fatal cases; here the organisms were seen to contain abundant pigment, whereas during life this was scarcely visible. Professor

Digitized by Google

Koch explains this by the suggestion that the parasites being deprived of oxygen either die or pass into a resting state in which they contract and their pigment accumulates in masses. The parasite of tropical malaria resembles those of tertian and quartan in forming spores when it ceases to grow. He has never observed this spore formation in the living blood, but in the spleen of subjects who have died from tropical malaria it can be observed. The spore-containing parasites are about half as large as those of tertian fever. Thus there were circular organisms with a central mass of pigment, others with a crenate or lobulated outline, others in which a small sphere of pigment was surrounded by a rosette of spores, and finally numerous free spores scattered amongst pigment residues.

The relation of these forms to the stages of the fever is as follows. During the febrile stage the blood only contains the young simple ring-shaped parasites. Their number is small, requiring careful search to detect them, and that may be fruitless. This paucity may explain the failure of many observers to detect parasites in tropical malaria. Towards the end of the paroxysm the parasites begin to grow but are still few in number, but when the attack is subsiding they assume the aspect of large rings. Their number corresponds with the severity of the attack, prolonged research being requisite to discover them in milder cases. As a rule, one parasite can be found in several microscopical fields, and sometimes every field contains from five to ten. In the two fatal cases which were examined there were about 10 per cent. in the one and 50 per cent. in the other of the red corpuscles in which parasites were seen. Where they are numerous one corpuscle may contain two or more parasites. The further stages of development cannot be observed in the blood drawn from the finger, but in the spleen and other organs, where the spore stage can be traced, the dissemination of spores and their attaching themselves to the blood corpuscles marks the onset of a fresh febrile paroxysm, the large forms having all disappeared. Professor Koch thus sums up these facts:—

1. Since the developmental process of the parasite lasts two days and the temperature curve is concomitantly repeated regularly every two days tropical malaria is a true tertian, which is distinguished from the tertian of Europe by the kind of parasite and the longer duration of the paroxysm.

2. If it be desired to determine the presence of parasites of tropical malaria the examination must be made as early as possible in the apyrexial period, because there is more certainty then to find the largest and most numerous parasites.

3. Since experience teaches that quinine acts best against malaria when it is given a few hours before the commencement of the attack, it should be employed in tropical malaria just when the large ring-shaped parasites appear in the blood.

In respect to the semilunar forms of parasites described by Laveran Professor Koch cannot agree in the idea that they have anything to do with a new generation of the parasites and a return of fever. He describes one case in which the fever spontaneously subsided, no quinine being given, and where the temperature remained low. Here, as in other cases, the early small rings were succeeded by larger ones as the paroxysm terminated, and then with the continuance of a lower temperature the ring-shaped organisms were entirely replaced by crescents which persisted for days without any fresh access of fever. And as this patient did not have any recurrence, but long remained perfectly well, Professor Koch thinks that in his case the crescents pointed to a condition of immunity having been established. So, again, in another case the presence of crescents corresponded with freedom from fever, the re-appearance of "rings," with a recurrence of the paroxysm. Moreover, cases of ring-shaped parasites were just those where the fever returned and where repeated doses of quinine were needed to prevent such recurrence. Relapses generally took place after from ten to twelve days, but they might be postponed by quinine short of actual arrest of the disease; but relapse was never seen later than a month. A recurrence of fever at a longer interval could not be with certainty considered a relapse; it might be a fresh infection. The shortest interval before a relapse may be taken as identical with the incubation period of tropical malaria on the hypothesis that the relapse is caused by a few germs left behind from the former attack. Erroneous views prevail as to the incubation of tropical malaria; thus it is often thought that exposure at a day's hunting or a wetting can be followed next day by a malarial attack, but this is hardly conceivable having regard to the fact that infection takes places through a few germs, which do not multiply like bacteria, but after two days' development increase only about tenfold. The time required for them to produce sufficient metabolic products to give rise to the characteristic febrile attack is therefore relatively long; in certain cases, such as the appearance of malaria on board ships which have been only a short time in contact with the land, there has been an incubation period of at least from ten to twelve days. This is borne out by an instance for which he was indebted to Dr. Spilker of H.M.S. *Condor*. On March 10th, 1897, the *Condor* anchored in the Moa Bay on the boundary of German and British East Africa, and in the evening of the 11th two boats with an officer and ten men were sent to shore. The boats went up a river surrounded by mangrove swamp and the crews had to pass the night in its vicinity. On March 23rd, or eleven days after this expedition, almost simultaneously in the afternoon, four men, and two days later two other men, from these boats' crews were attacked with typical tropical malaria. It is instructive that on the evening of the expedition the men had each taken 1 grm. of quinine and next morning 0·5 grm. as a prophylactic and yet some of them were attacked by malaria.

Professor Koch says that he has no positive proofs of the mode of infection, although he remarks that many surmises have been made. These various possibilities tend to become more and more restricted as knowledge of the nature of malaria increases, and as regards tropical malaria there may be said to be only two factors which can seriously be considered as media of infection. These are conveyance of the germs through drinking water and by mosquitos. The more he has studied the disease the more has he come to the opinion that the latter is probably the sole cause. It will be found that there is invariably a local and seasonal association between tropical malaria and mosquitos. There are places on the coast which are free from malaria, such as the island of Chole, to the south of the large island of Mafia. He visited this island, formerly used by the Zanzibar Arabs as a health resort, and found it to be the only place where he could sleep without a mosquito net. There is no malaria on the hills, where mosquitos, too, are absent. In the interior malaria diminishes together with mosquitos. At the seasons of the year when there are most mosquitos malaria is the most severe. His opinion is strengthened by the analogies between malaria and Texas fever and other tropical diseases of man and beast in which the parasites exclusively inhabit the blood. In all these diseases the infection is conveyed by blood-sucking insects and not by the direct transference by the insect from the blood of an infected animal to the other, but by the parasite developing in the insect's body and being thence transferred to the special host. Thus or similarly do mosquitos act in malaria, not that the mosquito immediately transfers the blood of one person to another, but that it first infects its own species. From numerous observations on hæmatozoal diseases in the lower animals and on attempts to infect animals with the malarial parasite Professor Koch came to the conclusion that for each parasite there is a special host and that man is the sole host of the malarial organism. Not that every man is equally susceptible to malaria. There occur in the tropics persons who have lived there many years without ever contracting malaria and it would seem as if there are whole races thus immune—for instance, the negro population of the East African coasts. The only case he met with in a coast-negro was that of a boatman of the Customs at Rufidjimundung, who had a mild attack, rapidly cured by a single dose of quinine. In this patient the ring-shaped parasites were in small number. On the other hand, the negroes of the Usambara region have no such immunity, although they in great part come from the same stock as the coast negroes. The other coloured folk, such as Indians and Chinese, who inhabit the region are not so immune, although he knew of some Indians who had been at Daressalam for years and were quite healthy. Bearing these facts in mind and also what has been said about the crescent-shaped bodies it seems clear that there is an actual immunity against malaria, which among the coast-negroes may be partly congenital, but with those who come from malaria-free countries must be acquired. Here, again, there is a remarkable analogy with Texas fever and Professor Koch ventures to express the hope that as in that disease so in tropical malaria an artificial immunity will one day be attained.

Tropical malaria is not so dangerous a disease as is

Digitized by Google

generally thought. There were but 2 deaths out of the 63 cases observed by Professor Koch, and he does not doubt that had these cases been recognised earlier and appropriately treated by quinine that they would have recovered. In all the other cases the effect of quinine was rapid and striking. As a rule 1 grm. sufficed to cause the disappearance of the parasites from the blood. It may be followed by another rise in temperature, but this rapidly subsides and during this final access he never found any parasites in the blood. This "after-fever" is probably due to the presence of the residues of the parasites and not to their vital activities. And it may be that the febrile paroxysms generally are due, not to the young parasites, but to the products set free by the death of the older generation. To ensure no recurrence of fever it is necessary to give another dose of quinine at the close of the "after fever." However, in order to exert its full action the drug should be given when the blood contains the ring-shaped organisms, and although the temperature serves as a guide the most certain test is that derived from microscopic examination. Hence the microscope is essential to the physician in the tropics both for early diagnosis and for treatment. For the earlier the quinine is given the better, the constitutional effects being in proportion to the number of attacks of fever which the patient has experienced. As the digestive organs are directly affected there is less chance of rapid absorption of quinine in cases where it is given after several attacks than when it is given quite early. It is important that the quinine should be of good quality and in a form for ready absorption. There is great tendency to relapse in tropical malaria. for even after quinine some germs may remain behind which serve to revive the infective process. These relapses weaken the power of the patient. The measures directed against such relapse serve also as prophylaxis and Professor Koch regrets that he has not been able to advance far in his researches in this important direction. He found that a dose of 0·5 grm. of quinine daily did not prevent relapse, but that 1 grm. given every fifth day in one case ensured freedom from relapse; in another there were slight and brief recurrences. Although he usually considers a dose of 0·5 grm. every third day sufficient for prophylaxis he cannot say that this is always sufficient, and that a single large dose does not ensure freedom from attack is evident from the cases which occurred amongst the crew of the *Condor*. If it should be finally found that a dose of 0·5 grm. is insufficient it might be preferable to give other drugs, as arsenic, since most patients do not bear well the long-continued dosage with quinine. In any case a prophylaxis so obtained can only be temporary, sufficing for the traveller or those who are only passing through the malarious districts. In the case of others exposed to infection so long as prophylaxis by drugs is not quite proved there are two other measures to be enforced. Firstly, all water used for drinking should be boiled, a fundamental thing essential in the prophylaxis of dysentery and other tropical diseases. Secondly, people must be protected during sleep by good mosquito nets. By "good" Professor Koch means one with sufficiently close meshes, which are often not used. Besides these personal measures the dangers of malaria may be mitigated by drainage, the cultivation of swamps, the proper disposal of fluid waste, and, above all, the fit construction of dwellings. In closing his report Professor Koch remarks that he has not seen in the subjects of tropical malaria any case of so-called malarial dyscrasia such as commonly occurs in other malarial districts. The attack itself is more severe, but the patient suffers less from after-effects than in tertian fever. Even children who have passed through the disease remain in good health. He also makes a few remarks on the cases of tertian which he had occasion to observe.

THE SANITARY PROGRESS AND INSTITUTIONS OF JAPAN.

THE Central Sanitary Bureau of the Japanese Ministry of the Interior has issued a report on the sanitary institutions of the Imperial Government of Japan. From this document it would appear that the unparalleled progress accomplished by Japan in the adoption of western civilisation includes all the leading phases of sanitary reform. It was in 1868 that the great Japanese revolution took place by which the feudal system was abolished. Government was then centralised in the hands of the Mikado. The Constitution was granted in February, 1889, and the first National Parliament met that year. The earliest attempt to establish a central authority to deal with sanitary matters was made in 1873, when a medical bureau was attached to the Education Department. Two years later this was transferred to the Home Office and was named the "Sanitary Bureau." Since 1875 all matters dealing with public health have been relegated to the Ministry of the Interior. Then also chemical laboratories were opened for the analysis of foods, drugs, &c. Japan is divided into forty-five prefectures or provinces, each having a governor depending on the Home Minister; then there are numerous subdivisions which correspond to our counties, urban and rural districts, wards, &c. The police office of these local authorities carries out sanitary measures and appoints local sanitary boards to study technical questions and advise. The Central Sanitary Bureau is divided into three sections, the health office, the epidemic prevention office, and the medical office. The first deals with drainage, water-supply, food-supply, &c.; the second with quarantines and epidemics; and the third with the control of medical education, midwives, pharmacies, &c. Previously to the organisation of this Bureau and since the revolution or commencement of the Meiji era the Government had issued many ordinances concerning the sale of opium, the vaccination of infants, &c., but there was no central control to see that these laws were uniformly applied. Also, although the Government was willing to apply the law, the nation was still ignorant and experience in England has taught us that the best of laws are of but little avail if the population are uneducated and indifferent. The Japanese Government therefore rightly concluded that education must precede legislation. Consequently the Government published the *Sanitary Bureau Magazine*, which was circulated among all officers, State functionaries, and others. Thus some knowledge as to the principles of sanitary administration was spread in the right quarters. This publication was commenced in April, 1876. In the course of time interest in public questions began to spread so rapidly that the *Magazine for the Improvement of Sanitary and Medical Knowledge* was started by private enterprise. Then many sanitary and medical societies were founded and these bodies also issued various publications and magazines. Thus by the year 1884 the Government found that it was no longer necessary to publish a magazine of its own; education on sanitary matters was now being actively spread independently of such Government intervention.

Needless to say that most of the knowledge thus acquired was imported from abroad. The European and American technical press was ransacked for data and information, and in the course of time a great number of Japanese were sent abroad to learn, observe, and report. The first investigator who received an official mission of this description was Dr. S. Nagayo, a professor at the Japanese Medical College, and he accompanied Prince Twakura, who was sent as Ambassador to Europe and the United States in 1871. Since then we have often had the opportunity of welcoming various Japanes delegates at sanitary and medical congresses and exhibitions. It may be remembered that there was a Japanese Section at the Health Exhibition held at South Kensington in 1884. Several Japanese medical men have studied at Professor Koch's laboratory in Berlin and in other European centres of scientific research. Also European men of science have been employed in Japan. For instance, Mr. Burton is Professor of Sanitary Engineering at the Japanese Imperial University and Sanitary Adviser to the Japanese Ministry of the Interior. Laboratories under the control of the Home Office have been established at Tokyo, Osaka and Yokohama, where chemical analyses are made both for the authorities and the public, and to which engineers are attached who undertake sanitary inspections. These laboratories have also their medical section, where drugs are tested and where some control is exercised over the sale of patent medicines. There is a very useful regulation to the effect that tradesmen must not quote any one sentence from the analyses made of their goods in these Government laboratories. If they wish to allude to the analyses they must quote it in its entirety, instead of only selecting a few favourable words.

The spread of Western ideas in Japan has not proved an unmixed blessing. Adulteration and fraudulent trading have followed in the wake. As the demand for European medicaments increased dishonest foreign merchants introduced a large quantity of inferior and adulterated drugs into Japan. Consequently a law had to be enacted to the effect that all

Digitized by Google

drugs landed in Japan must be taken to the State laboratories before they could be sold to the public. The first laboratory of this description was opened at Tokyo in 1874. In the following year another laboratory was established at Kyoto and a few months later a third was opened at Osaka. At first the analytical chemists were all foreigners, but in a few years the native chemists were fully qualified to take the work in their own hands and the employment of foreigners was gradually given up. The last of the foreign chemists was employed at the Yokahama Laboratory, but he died in 1884 and since that date the work of chemical analysis has been entirely in the hands of the Japanese. The most numerous analyses were of quinine and iodide of potassium, for these drugs were not only in great demand but were easily adulterated. At first a stamp was affixed to the drugs which had been examined, but in 1877 written reports were given instead mentioning the trade mark of the drug and stating whether it was suitable as a medicine. This caused the druggists to be more careful as to the quality of the chemicals, &c., which they imported into the country. Originally the examinations were gratuitous, but as the result was an increase of confidence, of sales, and of price, the Government felt justified in making the importers pay a fee for the analysis of the medicines, foods, drinks, &c., which they sold.

During the civil war and in consequence of cholera epidemics there was a greater demand for carbolic acid than could be supplied by foreign importations. The Government consequently started a factory of its own, and as Japan is rich in materials this manufacture of carbolic acid in time began to extend to other drugs and a general medicine manufacturing department was attached to the Tokyo Hygienic Laboratories. Subsequently a botanical garden for medicinal plants was established, and all these institutions were naturally also of great use to the students of medicine.

It was in 1884 that the Sanitary Museum was opened, and it contains not only a large library, but models of houses, sewers, drains, crematoria, waterworks, &c. In 1896 a Serum Institute was set up at Tokyo, under Dr. Tomaye Takagi, where the diphtheria antitoxin is produced. Two vaccine farms—one at Tokyo and one at Osaka—were likewise organised, whence vaccine lymph, taken from the calf, can be supplied throughout the country. This was commenced so far back as the year 1874, but foreign calves had to be procured, as the skin of the Japanese calves is generally too thick and too hard. The vaccine now produced in Japan in considered of such good quality that a large quantity is exported to Hong-Kong and other Chinese ports. The production of calf lymph was so great that in 1892 vaccination from the human arm was altogether abolished. But as there was money to be made many private persons began to make vaccine from calves, with the result that the quality soon became deteriorated and the Government had to interfere. The lymph is now provided by the National Vaccine Lymph Manufactory.

In dealing with epidemic diseases the Government gave a subsidy for the creation of an "Institution for the Investigation of Infectious Diseases," and in 1885 Dr. S. Kitasato was sent to Europe to study these questions. It was on his return in 1892 that this institution was opened in the park of Shiba, Tokyo. In 1877, during the civil war known as the South-West War, there was a terrible cholera epidemic and then many regulations were made to cope with the disease. Now the "Epidemic Prevention Board," which is a section of the Central Sanitary Bureau, deals with such matters and has the right to sanction the creation of any number of temporary epidemic inspection committees in all localities where their services are needed. They help to carry out the Law No. 36 of March 30th, 1897. This law applies to cholera, dysentery, typhoid fever, small-pox, typhus fever, scarlet fever, diphtheria, and plague. Other diseases may be added to this list, should occasion arise, by a special order from the Home Minister. According to this law it is the duty of all medical men to give instructions to families in which there are cases of epidemic disease as to the methods of disinfection which they must employ and also to notify the cases to the sanitary police. Whenever a case of infectious disease is believed to have occurred a physician must at once be called to examine the house and the patient. The medical man must report the results of such investigations at once to the sanitary police. The owner of the house is responsible for the carrying out of all measures of disinfection according to the directions of the medical practitioners or sanitary authorities. The same responsibility falls on the owners of neighbouring houses if the inhabitants have communicated with the infected person or house. If the measures of disinfection, &c. ordered are not carried out by the person concerned the local authority will undertake the work and recover the cost from the house-owner. The local authorities have the right to remove patients to fever hospitals and to isolate the patient's family in a house set aside for that purpose. When judged necessary a house or block of houses and all the inhabitants may be isolated from the rest of the community by a sanitary cordon for a period of five days in cases of cholera and for a period of seven days in cases of typhus fever. No clothing, &c., infected, or presumed to be infected, must be used, thrown away, given away, or be sent to be washed. Nor must the body of any person dying from infectious disease be removed in the ordinary manner. Such corpses must be cremated unless special permission has been given for their burial. Sanitary officers can obtain a written order giving them the right of entry into any private house in case of epidemic disease. The local authorities must organise staffs of disinfectors under the direction of medical men and provide isolation hospitals and isolation houses.

With regard to quarantine regulations ships arriving from ports declared to be infected by the Ministry of the Interior must proceed to one of the five ports where quarantine hospitals, &c., have been provided—namely, Nagasaki, Shimonoseki, Kōbe, Yokohama, and Hakodati. Here they must display the yellow flag and await the arrival of the port sanitary authorities. Ships which have been five days at sea and are in a satisfactory condition are not detained after inspection. If there is disease on board then the ship must be disinfected and the passengers and crew kept in quarantine for seven days in cases of plague or typhus fever and for five days in cases of cholera. Somewhat similar regulations are applied to railway trains. If a death occurs in a railway carriage the goods and passengers may be isolated and disinfected. Should this happen at a small station where no means of disinfecting exist the railway carriage must be sealed up and its passengers and contents sent on to a larger station, where all that is required will be found. Inspectors may accompany the carriage to see that these regulations are duly observed and that the passengers do not attempt to escape.

The local authorities have the right to isolate a part or the whole of a town or village. They can also forbid meetings, religious festivals, or theatrical performances when such gatherings may tend to spread an epidemic. They may stop any goods in transit which are likely to be infected, such as old rags, personal linen, &c., and these may be destroyed if necessary. In the same manner they can stop the sale or distribution of any food or drink which may be contaminated and they have the right to destroy the same. The local authority can also enforce general sanitary measures, such as the improvement of drains, the closing of wells, &c.; and to assist small local authorities the provincial authorities must bear a sixth of the expense entailed. If all such duties are not performed in the proper time the persons responsible are liable to be fined; and medical practitioners who do not notify cases of infectious disease within twelve hours are liable to a fine of from 5 to 50 yen and a yen is equal to about 3*s*. 6*d*. All householders and others who, by bribery and other means, seek to avoid disinfection, &c., are to be fined at least 2 yen. In disinfecting all drains, dust heaps, &c., must be cleaned out, the contents burnt on the spot or removed to a suitable place in closed vessels, and the walls and floors must be washed with solutions of carbolic acid or corrosive sublimate. Other objects must be disinfected by boiling, by steam, or by burning. In the isolation or fever hospitals there should be one head physician and an assistant physician for every 15 to 20 patients.

Vaccination and revaccination are rendered compulsory by the law of 1885 and the first clause is as follows: "After a child is born he or she must be vaccinated within one year, and if unsuccessful vaccination must again be performed within the next year; and even if successful revaccination must be performed every five or seven years afterwards." A fine not exceeding 50 yen is imposed on persons who do not observe this law.

With regard to syphilis, the first hospital for venereal disease was established at Yokohama in 1867 by the Feudal Government of Tokugawa and shortly afterwards similar hospitals were opened at Kōbe and Nagasaki, and here prostitutes were examined. The Home Office issued instructions in April 1876, to other local authorities besides those of the

Digitized by Google

three ports mentioned, instructing them to make arrangements for the medical examination of prostitutes. These examinations generally take place once a week and women who are found to be diseased are immediately taken to the hospital and their licences confiscated.

Such, briefly, are some of the principal regulations relating to the preservation of public health in Japan. Some of them, it will be seen, are more severe than our English sanitary laws, and there is hardly a phase of sanitary improvement attempted in Europe which has not been imitated by the Japanese. In some instances the Japanese legislature has been more bold and sweeping in the measures he has approved than the more experienced and older legislatures of Europe. Of course, it still remains to be seen how far these paper reforms have been carried out in actual practice; but it is only those who have made careful investigations on the spot who can venture to express an opinion as to the practical results. In any case, it is most satisfactory to see that the Government has taken the lead. If the people have not yet fully appreciated the advantages of the sanitary legislation offered them they have differed in this respect from the people of most other countries. In time the advantages of good laws obtain recognition and the whole community helps to carry them out. In the meanwhile their enactment serves as an object lesson in the education of the people.

THE SANITARY INSTITUTE: MEETING AT BIRMINGHAM.

THE seventeenth annual congress of the Sanitary Institute was opened in Birmingham on Tuesday, Sept. 27th, under the Presidency of Sir JOSEPH FAYRER, Bart., K.C.S.I., M.D. Edin., F.R.S. Councillor C. G. Beale, the Lord Mayor of Birmingham, received the members in the Council House, and afterwards took the chair at a public luncheon.

PRESIDENTIAL ADDRESS.

In the afternoon the general meeting of the congress took place at the Birmingham and Midland Institute, when Sir Joseph Fayrer delivered his Presidential Address on

The Progress of Preventive Medicine.

Sir JOSEPH FAYRER commenced by pointing out that in an age of progress and discovery, when intellectual activity was very great and when the practical applications of science were most remarkable, nothing in Her Majesty's glorious reign formed a fitter subject for congratulation than the improvements which had taken place in the vital statistics of our country as shown by the reduced mortality rate, the improved expectation of life, and the disappearance of potential causes of death. In bringing about these desirable results the Sanitary Institute, he claimed, had taken an important part. Public health was now cared for in a sense which was utterly unknown in the past; houses were better built; sewerage, drainage, and ventilation were provided for; the land was better cultivated, the subsoil better drained, the absolute importance of pure drinking water was recognised, food was more varied and more nutritious in its character, and clothing was better adapted to climate. Were all the existing official provisions enforced little would remain to be desired on the part of the Government, but as some of these Acts were not compulsory, and as others were neglected, much of their benefit was lost. Though education had done much, as far as the better classes were concerned, and upwards of 200 millions had been spent on sanitary work, with great benefit to the public health, popular teaching and example and the general diffusion of education were still necessary in order to convince the proletariat of what so intimately concerned their vital interests. The death-rate was susceptible of further diminution, expectancy of life might be enhanced, and the general conditions of living and exemption from certain forms of disease were by no means as perfect as they might be. Tainted water was still drunk, as was illustrated by the outbreaks of typhoid fever at Maidstone and Lynn last year, chimneys still vomited forth chemical fumes, rivers were still polluted, cesspools and imperfect drains, badly-constructed and ill-ventilated houses still defied alike sanitary law and common sense; and it would perhaps not be until the more complete organisation of the public health administration under a Minister of Public Health had been effected that the full benefits of sanitary legislation would be realised and the people attain to that standard of health and duration of life for which they had a right to hope.

Nevertheless, when we contrasted the present state of our country with its 29,000,000 of inhabitants with that of the Elizabethan era with its 4,000,000 we had ample proof of the ignorance of science in those days and of the great improvements which had taken place in these. A brief inquiry into the statistics of some well-known diseases would show that they had become less severe in their incidence, if not less frequent in their recurrence. In small-pox, for example, there had been a great reduction, more so than in any other disease. Since the passing of the first Vaccination Act in 1841 the death-rate had fallen from 576 per 1,000,000 to 20 per 1,000,000 in 1891–95. Vaccination, isolation, attention to rational treatment, whether therapeutic or hygienic, had preceded or accompanied, and, as most people believed, induced these results; and theories which ignored vaccination as a preventive must, it appeared to him, necessarily be rejected until a better explanation of the cause of the diminished incidence and mortality from the disease could be offered. As to the value of vaccination, all the evidence which was forthcoming seemed to show that there could be no doubt of it. As to the methods by which every individual was to be vaccinated or revaccinated, that was a subject for the State to determine. That the Acts in existence up to the present time were inadequate to this end was plainly shown by the fact that large and increasing numbers of the population were known to be unvaccinated despite their compulsory character. Lord Lister said in his speech in the House of Lords last August that one-third of the children born were unvaccinated and that one-fourth of the boards of guardians did not put the law in force. The most recent Vaccination Act, whatever might be its advantages, was certainly defective in this: that it made no provision for revaccination, the necessity for which was universally admitted by the medical profession, whilst it was very doubtful whether the modification of the compulsory clauses would have the effect of extending vaccination. This remained to be seen during the five years for which the new Act was to be in operation. Whatever the Government might have thought proper to enact, there seemed good reason to believe that as far as it was concerned faith in vaccination was as unshaken as it was in the minds of the Royal College of Physicians of London, who had recently expressed their unaltered conviction that vaccination "properly performed and duly repeated is the only known preventive of small-pox." Sir Joseph Fayrer then went on to consider the death-rate. In 1838, he said, the death-rate from fever at all ages was 1053 per 1,000,000, in 1891–95 it was 185 per 1,000,000. Fevers notably flourished where sanitation was defective, and as dirt, overcrowding, and destitution had been diminished so had typhus fever disappeared, whilst with improved drainage, the removal of excretal filth, and the supply of pure water enteric fever had become less. There was reason to think that cholera was similarly influenced, for though it had appeared in England several times since its first invasion in 1831, as in 1845–49, 1853–54, 1865–66, and even since at Grimsby in 1893, yet its virulence and activity had been gradually diminishing. Happily, the antiquated system of prevention by coercion had in England been replaced by that of sanitary measures and isolation and it was to the wise and judicious exercise of those by the medical authorities of the Local Government Board and of the local authorities throughout the kingdom that whilst neighbouring countries in the full practice of coercion and quarantine were decimated England had lately remained almost exempt. Since 1861 the scarlet fever death-rate had been reduced 81 per cent., but the diphtheria death-rate was now very much the same as it was over thirty years ago. In 1835–42 the death-rate from tuberculous disease was 3959 per 1,000,000; in 1891–95 it was 2124, not so remarkable a diminution as in the other diseases, but serving to show that sanitation had done good by helping to improve the ill-ventilated crowded dwellings, damp, water-logged soil, and impure water, and that protection against noxious trades had been of value. As to malarial diseases, they might include them in England among those which had become all but extinct. It was not to be supposed that zymotic disease could be altogether exterminated, but they could modify and diminish its incidence. But the scope and aim of sanitary science in its preventive

Digitized by Google

aspects should not be limited to the consideration of zymotic disease. It should extend to the results of abnormal social conditions arising out of the strain and struggle for existence, involving over competition in various occupations by which life was supported, and under the pressure of which so many lost their health or even succumbed. The over-pressure now exerted on the younger of the rising generation might not only involve the risk of miscarriage of true education, but dangers against which it was as much the duty of preventive medicine to guard young people as it was to protect them from scarlet fever, small-pox, measles, cholera, or any other disease. One indication of the effect of sanitary work was observed in the death-rate of the country. In 1841–50 it stood at 22·4 per 1000; in 1891–95 at 18·7 per 1000; though for the four years 1890–93 it had risen owing to epidemic influenza.

The condition of India, continued Sir Joseph Fayrer, speaking from great personal experience, presented an admirable example of the value of preventive medicine and hygienic methods. In 1859 an inquiry was instituted into the mortality of the European and subsequently the Indian army and gaol and civil populations. It was ascertained as one result of the investigation that the ordinary death-rate of the British soldier had stood for a long period of time at the appalling figure of 84·6 per 1000 from 1800–30 and at 56·70 per 1000 from 1830–56. Certain sanitary changes and improvements in the housing, clothing, food, and discipline of the soldiers were then enforced and were followed by a signal decline in the death-rate, though marked by fluctuations. In 1886 it was 15·8 per 1000 and in 1895 15·26 per 1000, the intervening years showing slight fluctuations. The death-rate of the native army did not show so great a diminution, but here, too, there was improvement. In 1889 the death-rate was 12·94 per 1000 and in 1895 11·60. After referring briefly to the unfortunate spread of syphilis among our Indian troops Sir Joseph Fayrer concluded by an eloquent exhortation to his hearers not to consider that a knowledge of bacteriology, in spite of the magnificent work of bacteriologists, would solve all sanitary problems. There were, he pointed out, other factors of no less importance to be considered. While it was of the utmost significance that we should be able to demonstrate the actual cause, whether a micro-organism or not, on the other hand it was not of less importance that we should know all the conditions under which this cause became effective. It was not enough to know the seed: it was necessary that we should also know the nature of the soil and all the conditions which determined whether the seed was to grow and multiply or to remain inert and harmless. If we could learn how to destroy the seed of disease or sterilise the soil in which it attained its full development, or if we could neutralise the favouring conditions and so prevent or impede its growth, then we should have solved a great problem and conferred a lasting benefit on mankind. Much of this had already been done and the splendid work of Pasteur, Koch, Lister, Burdon Sanderson, and Sims Woodhead, among others, was almost daily adding to our knowledge of zymotic disease. It could not be doubted that the Sanitary Institute had contributed its share to the advance which public health had made since its foundation.

Earl BEAUCHAMP proposed a vote of thanks to the President and remarked that he was sorry that no member of the Government was present to have heard Sir Joseph Fayrer's views upon the subject of vaccination.

Councillor MARTINEAU seconded the motion, which was carried with acclamation.

CONFERENCES.

A conference of medical officers of health was held in connexion with the congress under the presidency of Dr. J. C. McVail, the substance of whose inaugural address we publish on page 849 of this issue.

A conference of municipal representatives was held under the presidency of Alderman Cook, chairman of the Health Committee of the Birmingham City Council, at which some interesting papers were read. Dr. J. F. J. Sykes, medical officer of health of St. Pancras, read a paper on the Dwelling Accommodation of the Working Classes in Large Cities, and Mr. E. Parkes, M.P. for Birmingham (Central Division), read a paper upon the Municipal Management of Public Slaughter-houses.

A conference of municipal engineers was presided over by Mr. T. de Courcy Meade, whose presidential address dealt with the By-laws concerned in the Construction of New Streets and Buildings.

A conference on Domestic Hygiene was presided over by Mrs. Beale, the Lady Mayoress, at which Miss Mary Sturge read a paper on the Claims of Childhood, which excited some discussion.

EXHIBITION OF SANITARY APPLIANCES.

In the evening of the opening day the Lord Mayor opened a Health Exhibition in Bingley Hall in the presence of members of the congress and many of the leading citizens of Birmingham. The exhibition, which included all descriptions of sanitary appliances, was illustrative of the advances which have been made during recent years in public health.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6520 births and 5072 deaths were registered during the week ending Sept. 24th. The annual rate of mortality in these towns, which had been 24·6 and 24·0 per 1000 in the two preceding weeks, further declined last week to 23·6. In London the rate was 21·6 per 1000, while it averaged 24·9 in the thirty-two provincial towns. The lowest death-rates in these towns were 15·9 in Portsmouth, 16·2 in West Ham, 16·4 in Swansea, and 18·5 in Leicester; the highest rates were 32·4 in Manchester, 35·8 in Salford, 37·0 in Sunderland, and 38·7 in Gateshead. The 5072 deaths in these towns included 1454 which were referred to the principal zymotic diseases, against 1575 and 1545 in the two preceding weeks; of these, 1238 resulted from diarrhœa, 65 from whooping-cough, 51 from diphtheria, 45 from "fever" (principally enteric), 28 from scarlet fever, and 27 from measles. The lowest death-rates from these diseases were recorded in West Ham, Derby, Cardiff, and Portsmouth; and the highest rates in Bolton, Salford, Sunderland, and Gateshead. The greatest mortality from measles occurred in Plymouth; from whooping-cough and from "fever" in Sunderland; and from diarrhœa in Norwich, Salford, Bolton, Hull, Sunderland, and Gateshead. The mortality from scarlet fever showed no marked excess in any of the large towns. The 51 deaths from diphtheria included 29 in London, 5 in Swansea, and 4 in Liverpool. No fatal case of small-pox was registered during the week under notice in any of the thirty-three large towns; and only 1 small-pox patient was under treatment in the Metropolitan Asylum Hospitals on Saturday last (Sept. 24th). The number of scarlet fever patients in these hospitals and in the London Fever Hospital on the same date was 2353, against 2240, 2300, and 2319 on the three preceding Saturdays; 288 new cases were admitted during the week, against 238, 273, and 242 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 130 and 135 in the two preceding weeks, further rose to 157 last week, but were 19 below the corrected average. The causes of 50, or 1·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Bradford, Leeds, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Preston, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·0 and 18·8 per 1000 in the two preceding weeks, rose again to 19·7 during the week ending Sept. 24th, but was 3·9 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·6 in Perth and 14·1 in Aberdeen to 20·1 in Edinburgh and 21·4 in Glasgow. The 595 deaths in these towns included 104 which were referred to diarrhœa, 22 to whooping-cough, 13 to "fever," 7 to diphtheria, 6 to scarlet fever, and 4 to measles. In all, 156 deaths resulted from these principal zymotic diseases against 140 and 157 in the two preceding weeks. These 156 deaths were equal to an annual rate of 5·2 per 1000, which was 1·6 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had increased from 81 to 110 in the

Digitized by Google

three preceding weeks, declined to 104 last week, of which 55 occurred in Glasgow, 20 in Edinburgh, 13 in Dundee, and 7 in Greenock. The 22 deaths from whooping-cough exceeded by one the number in the preceding week, and included 10 in Glasgow, and 5 in Aberdeen. The deaths referred to different forms of "fever" which had been 9 in each of the five preceding weeks, rose to 13 last week, of which 6 occurred in Paisley, 4 in Glasgow, and 2 in Edinburgh. The 7 fatal cases of diphtheria showed a further increase upon those recorded in recent weeks, and included 5 in Glasgow; and of the 6 deaths from scarlet fever 4 occurred in Edinburgh and 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 100 and 68 in the two preceding weeks, rose again to 85 last week, but were 11 below the number in the corresponding period of last year. The causes of 29, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 30·7 and 27·1 per 1000 in the two preceding weeks, further declined to 27·0 during the week ending Sept. 24th. During the past four weeks the rate of mortality in the city averaged 28·1 per 1000, the rate during the same period being 22·0 in London and 19·5 in Edinburgh. The 181 deaths registered in Dublin last week were within one of the number in the preceding week, and included 32 which were referred to the principal zymotic diseases, against 54 and 35 in the two preceding weeks; of these, 20 resulted from diarrhœa, 6 from "fever," 4 from whooping-cough, 1 from measles, 1 from scarlet-fever, and not one either from small-pox or diphtheria. These 32 deaths were equal to an annual rate of 4·8 per 1000, the zymotic death-rate during the same period being 5·1 both in London and in Edinburgh. The fatal cases of diarrhœa, which had been 38 and 26 in the two preceding weeks, further declined to 20 last week. The deaths referred to different forms of "fever," which had been 5 and 3 in the two preceding weeks, rose again to 6 last week, a higher number than in any week since March last. The 4 fatal cases of whooping-cough corresponded with the number in the preceding week. The 181 deaths registered in Dublin last week included 61 of infants under one year of age, and 32 of persons aged upwards of sixty years; the deaths of infants showed an increase, while those of elderly persons showed a further decline from recent weekly numbers. One inquest case and 1 death from violence were registered; and 51, or nearly a third, of the deaths occurred in public institutions. The causes of 14, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: Benjamin G. Heather to the *Pembroke*, additional for disposal; E. R. Grazebrook to the *Empress of India;* and J. H. Fergusson to the *Thunderer*. Surgeons and Agents: Andrew Cluckie at Stranraer and Cairn Ryan, and Welby J. Anson at Whithaven.

ROYAL ARMY MEDICAL CORPS.

Major Maurice O'Connor Drury having joined at Netley on Sept. 23rd is posted to the Medical Division of the Royal Victoria Hospital. Lieutenant-Colonel Peyton proceeds from Holywood to Limerick for duty.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Captain Deare, Officiating Civil Surgeon of Midnapore, are placed temporarily at the disposal of the Chairman of the Corporation of Calcutta. Mr. Fink, Officiating Civil Medical Officer of Bhagalpur, is appointed temporarily to act as Civil Medical Officer at Midnapore during the absence on deputation of Major Walsh, or until further orders. Colonel A. Stephen (Bengal), Principal Medical Officer and Sanitary Commissioner, Assam District, is appointed to officiate as Inspector-General of Civil Hospitals, Punjab, during the absence on furlough of Colonel D. O'C. Raye until further orders. The services of Major Bannerman are replaced at the disposal of the Government of India.

VOLUNTEER CORPS.

Artillery: 1st Cornwall (Duke of Cornwall's) (Western Division, Royal Artillery): John Alfred Fox is re-appointed Surgeon-Lieutenant. *Rifle:* The Queen's Rifle Volunteer Brigade, the Royal Scots (Lothian Regiment): The undermentioned Surgeon-Lieutenants to be Surgeon-Captains:—J. A. Clark, A. Macdonald, C. B. Ker, and J. Pirie. 1st Volunteer Battalion the Royal Sussex Regiment: Surgeon-Lieutenant C. J. Jacomb-Hood to be Surgeon-Captain. 5th Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant A. A. Abraham to be Surgeon-Captain.

THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The following officers have recently passed the proficiency examination for volunteer medical officers, thereby earning the higher capitation grant for the corps and becoming entitled to promotion after completing the necessary period of service:—Surgeon-Major W. H. Webb, 5th Volunteer Battalion Devonshire Regiment; Surgeon-Lieutenant J. Jackson Clarke, Commanding Bearer Company, North London Volunteer Brigade; Surgeon-Lieutenant W. G. Owen, 1st Cheshire and Carnarvonshire Volunteer Artillery; Surgeon-Lieutenant R. Mair, 1st Roxburgh and Selkirk Rifle Volunteers; Surgeon-Lieutenant G. Black, 2nd Volunteer Battalion Royal Sussex Regiment; Surgeon-Lieutenant J. A. Wilson, 3rd Volunteer Battalion Highland Light Infantry; Surgeon-Lieutenant H. Syers, 3rd Middlesex Volunteer Artillery; Surgeon-Lieutenant C. S. de Segundo, 20th Middlesex (Artists) Rifle Volunteers; Surgeon-Lieutenant F. S. Hogg, 20th Middlesex (Artists) Rifle Volunteers; Surgeon-Lieutenant E. Goddard, 9th Middlesex (Harrow) Rifle Volunteers; Surgeon-Lieutenant A. Duke, 1st Tynemouth Volunteer Artillery; Surgeon-Lieutenant E. C. Palmer, 1st Volunteer Battalion Lincolnshire Regiment; Surgeon-Lieutenant J. D. Farquharson, 1st Newcastle-on-Tyne Volunteer Artillery; Surgeon-Lieutenant D. J. Lawson, 1st Dorsetshire Volunteer Artillery; Surgeon-Lieutenant J. N. Brown, 5th West Middlesex Rifle Volunteers; Surgeon-Lieutenant D. R. Dobie, 2nd Volunteer Battalion the King's Scottish Borderers; Surgeon-Lieutenant C. J. Beattie, 18th Middlesex Rifle Volunteers; Surgeon-Lieutenant I. McBourke, 18th Middlesex Rifle Volunteers; Surgeon-Lieutenant H. L. Wilks, 1st Wiltshire Rifle Volunteers; Surgeon-Lieutenant W. Boyd, 1st Volunteer Battalion the Royal Scots Fusiliers; Surgeon-Lieutenant P. Shaw, 1st Volunteer Battalion Highland Light Infantry; Surgeon-Lieutenant A. Abraham, 5th Volunteer Battalion the Durham Light Infantry; Surgeon-Lieutenant W. J. Edwards, Tees Division Submarine Miners Royal Engineer Volunteers; Surgeon-Lieutenant E. G. Peck, 2nd West Riding of Yorkshire Volunteer Artillery; Surgeon-Lieutenant D. King-Smith, 48th Highlanders of Canada; Surgeon-Lieutenant R. L. Clark, 1st Cumberland Volunteer Artillery; Surgeon-Lieutenant S. L. Potter, 1st Volunteer Battalion the King's Own Yorkshire; Surgeon-Lieutenant E. V. Eames, 1st Volunteer Battalion the Derbyshire Regiment; Surgeon-Lieutenant J. C. Fenwick, 3rd Volunteer Battalion the Durham Light Infantry; Surgeon-Lieutenant J. G. Ronald, 4th Volunteer Battalion the Argyll and Sutherland Highlanders; Surgeon-Lieutenant W. H. Vickery, 3rd Volunteer Battalion the Northumberland Fusiliers; Surgeon-Lieutenant E. Farr, 2nd Volunteer Battalion Middlesex Regiment; Surgeon-Lieutenant R. Shearer, Robin Hood Rifle Volunteers; and Surgeon-Lieutenant F. Grindon, Bearer Company, Home Counties Volunteer Brigade.

THE RED CROSS SOCIETY AND THE NILE CAMPAIGN.

The *Mayflower*, a stern-paddle steamer, 140 ft. long, has been chartered by the National Society for Aid to Sick and Wounded in War (the British Red Cross Society) to convey sick and wounded soldiers from the Soudan between Assouan and Cairo. She carries two medical officers and eight men of the Royal Army Medical Corps, lent by the Government, and two nurses sent out by the society. Reconstructed from a pleasure vessel into a hospital ship to hold 52 sick and wounded and on an emergency 72 patients, she is fitted out with the most modern medical and surgical appliances and medical comforts of every description. The sick and wounded will thus enjoy the luxury of being conveyed by river, and will be saved the heat, choking dust, and the severe discomforts of the railway journey of about 600 miles between Assouan and Cairo, which a high authority has described as the worst part of the transit between Khartoum and Cairo. The ship was inspected by the general officer

Digitized by Google

commanding, and she started on Sept. 6th on her first voyage of mercy, leaving Assouan for Cairo on Sept. 15th with twenty-eight wounded and twenty-four sick, including the following officers: Molyneux, Hopkinson, Clark, Geoghegan, Sloggett, and Dyke.

WINTER SESSION OF THE ARMY MEDICAL SCHOOL, NETLEY.

The seventy-seventh session of the Army Medical School will commence on Monday, Oct. 3rd. The surgeons on probation will join at Netley on Oct. 1st. The following are the lists of those who are to attend the school, having obtained places at the recent competition. In addition to these gentlemen we understand that others will attend the school, sixteen nominations having been offered among the medical schools of the United Kingdom under Article 350 of the Pay Warrant.

ROYAL ARMY MEDICAL CORPS.

F. Warren.	G. W. G. Jones.
J. E. Hodgson.	J. W. H. Houghton.
H. P. W. Barrow.	H. S. Taylor.
M. H. G. Fell.	A. L. Scott.
T. C. Lauder.	J. W. Leake.
J. G. Gill.	R. H. Lloyd.
W. B. Winkfield.	D. E. Curme.
G. H. Goddard.	G. M. Goldsmith.

INDIAN MEDICAL SERVICE.

J. C. H. Leicester.	L. E. L. Parker.
H. Innes.	T. S. Ross.
W. S. Willmore.	J. N. Walker.

H. M. Cruddas.	G. King.
C. F. Weinman.	P. P. Atal.
E. L. Ward.	W. McM. Pearson.

A PEERAGE FOR THE SIRDAR.

Medical officers, in common with everybody else, will have been much gratified at the announcement that the Queen has been pleased to confer the dignity of a Peerage of the United Kingdom upon the Sirdar, Major-General Kitchener, in recognition of his brilliant military services in Egypt, more especially in connexion with his late battles at Atbara and Omdurman and the taking of Khartoum. The Sirdar has been very thorough in all that he has undertaken, he is a first rate organiser, and has shown that he possesses strategical and tactical skill of no mean order. He has successfully carried out his intentions with what may be fitly termed a scientific precision, which reflects great honour and credit on the scientific corps to which he belongs and awakens the sympathetic admiration of the other scientific branches of the service and of the army in general. It was fitting that he should receive a national recognition of the services which he has rendered to the Queen and to the country.

THE INDIAN TROOPING SEASON AND THE ROYAL ARMY MEDICAL CORPS.

The *Times of India* of Sept. 10th announces the following as the order in which the officers of the Royal Army Medical Corps will proceed home this trooping season:—

Term expired, in Nubia, Oct. 7th—Majors Lucas and Stables and Captains Mason and Potter; Simla, Oct. 14th—Majors Russell and Baird and Captains Poole and Faichnie; Dilwara, Nov. 11th—Majors Gerrard and Birch and Captains Knaggs and Begbie; Dunera, Nov. 26th—Majors Kirkpatrick and James and Captains Tacker and Buist; Nubia, Dec. 8th—Majors Winter, Anderson, and Hathaway, and Captain Alexander; Simla, Jan. 3rd—Majors Nichol, Johnston, and Daly, and Captain Crawford; Dilwara, Jan. 13th—Majors Nicholson, Burtchaell, and Fryer, and Captain Symons; Dunera, Jan. 20th—Lieutenant-Colonel Thomsett, Majors Mills and E. Davies, and Captains Holt and Lawson; Nubia, Feb. 10th—Lieutenant-Colonel Bennett, Majors Cree and Skinner, and Captains Buchanan and Hennessy; Simla, March 3rd—Majors Poole, Keogh, and Melville, and Captains Pilcher and Tyacke; Dilwara, March 18th—Lieutenant-Colonel May, Majors Wills and Woodhouse, and Captains Faichnie and Kellie; Dunera, March 25th—Lieutenant-Colonel Anderson, Majors Fitzgerald and A. M. Davies, and Captains Withers and Martin.

THE KHYBER.

The improvement in the general health of the troops in the Khyber still continues and their health may now be said to be fairly good. The question of the control of the Khyber and the settlement of the frontier has been referred home to the Secretary of State for final decision. It is practically settled that the control will be handed over from the Punjab to the Imperial Government and that a large fort will be built at the entrance of the Khyber Pass.

The following officers of the Royal Army Medical Corps will, under the terms of the Royal Warrant, retire from the Army this month: Lieutenant-Colonel A. Anderson (Madras), Surgeon-General J. B. Hamilton, P.M.O., Western District, and Lieutenant-Colonel R. H. Robinson.

Lieutenant-Colonel C. Swaine, I.M.S., has been confirmed as Principal Medical Officer, Hyderabad Contingent.

Correspondence.

"Audi alteram partem."

"THE PLAISTOW MATERNITY CHARITY."

To the Editors of THE LANCET.

SIRS,—It was perhaps excusable that Mr. F. R. Humphreys should have fallen into the error which produced his lengthy letter in THE LANCET of Sept. 24th; it is comprehensible that, having fallen into this error, he should have communicated his opinion on the subject to THE LANCET: but that he should, on such slight grounds, have attacked a large and representative body of his brother practitioners with that species of sneer concerning the filling of pockets which is most often heard amongst the more ignorant section of the laity, is hardly either excusable or comprehensible.

The action of the individual practitioner quoted and commented upon by Mr. Humphreys was never advocated or endorsed by the Executive Council. The incident was related to THE LANCET Commissioner and repeated by him, not as an example of the methods of the society, but rather as an illustration of the extremely unsatisfactory state of things fostered by the abuses at present prevalent in the system of the Plaistow Maternity Charity—a state of things which might easily lead an individual practitioner to a course of action which on reflection he might regret.

If Mr. Humphreys will make himself acquainted with our official methods and literature he will recognise that his fulminations concerning men "bound by rules which disregard everything but the pecuniary necessities of trade" are irrelevant and somewhat ridiculous. The members of our society are bound by no rules whatever as to personal conduct, except those of the generally accepted unwritten codes of personal honour and professional ethics.

In conclusion, I may state that I shall be glad to forward copies of the registered objects and rules of the society to any medical man who is interested in the subject.

I am, Sirs, yours faithfully,

MURTAUGH HOUGHTON,

Hon. Secretary, East Suburban Medical Protection and Medico-Ethical Society, Limited, West Ham Hospital, E.

Sept. 27th, 1898.

THE OPERATIVE TREATMENT OF MYOPIA.

To the Editors of THE LANCET.

SIRS,—To those who during the last few years have taken some pains to test the value of this method of treatment Dr. Kenneth Scott's[1] reasons for condemning it will appear wholly inadequate. These he sums up in the concluding paragraph of his article:—

The method of treatment in question is one which is avowedly sound in theory and also quite feasible in practice, but it is absolutely imperative that it should be entirely regarded from the patient's point of view, and *consequently* should be placed in abeyance until the operation for the extraction of the lens from the eye by whatever method has been resolved into one which is entirely free from all risk of the onset of any after inflammation.

That this and every other treatment should be considered entirely from the patient's point of view is a platitude, but the conclusion that the writer draws from it is surely unsound. If absolute freedom from risk is to be a *sine qua non* of an operation every surgical proceeding will "remain in abeyance" till the Greek Kalends. It is for the surgeon to weigh the risks and advantages of the treatment and to place them before the patient in such a way that he may be able to form a wise decision.

Dr. Scott compares the operation for high myopia with that of the extraction of a senile cataract and because failure occasionally results from the latter he thinks the former should not be attempted. The failures after extraction, however, are under 5 per cent., the patients are all past middle life, and many of them are in feeble health. There

[1] THE LANCET, Sept. 24th, 1898, p. 805.

Digitized by Google

is, moreover, little analogy between the operation of extraction and that of discission with subsequent evacuation of the lens matter, which is the recognised proceeding for high myopia. It will seem to most who have seriously considered the subject that the chief question to be considered is that which has been excluded by Dr. Scott—namely, Does the operation render the eye more liable to detachment of the retina? The treatment has been extensively practised both on the continent and in this country and the results hitherto have been very satisfactory. It not merely enables many patients to dispense with glasses—in itself a great boon to individuals in some walks of life—but it gives them good vision without glasses in place of bad vision with them.

It is, of course, possible that in after years eyes operated on in this manner may go wrong; there does not, however, seem to be any reasonable ground for such an apprehension. Such an objection might be urged with equal force against any new proceeding, but we shall best consult the interests of our patients, not by refusing to adopt new methods on account of objections which are purely hypothetical, but by adopting them cautiously and selecting at first only the most promising cases. Although I am myself much impressed with the value of this treatment in suitable cases I think it prudent at present to confine it to one eye.

I am, Sirs, yours faithfully,

Cavendish-square, W., Sept. 26th, 1898. W. ADAMS FROST.

EAST LONDON WATER.

To the Editors of THE LANCET.

SIRS,—The following is a report on a series of samples taken at 6, Holly-road, Leytonstone. Five samples were taken: the first on Sept. 9th at 7.30 A.M.; the second on Sept 11th at 12 noon; the third on Sept. 12th at 2 P.M.; the fourth on Sept. 14th at 8.30 A.M.; and the fifth on Sept. 19th at 8.15 A.M. The samples were taken with the following precautions: six bucketfuls of water were drawn from the tap on the service pipe and a sample was then taken in a vessel sterilised at 160° C. for an hour. A given quantity was then measured off in a sterilised pipette and added to a tube of liquefied gelatin and plated; the plates were incubated at from 20° to 23° C. The colonies were enumerated upon the second day. The gelatin used was 10 per cent. gelatin in nutrient broth (0·5 kilo. of meat per litre) and with an alkalinity of 3 c.c. normal NaOH per litre. The amount of water taken varied from 0·5 to 0·05 c.c.

Sample 1, taken on Sept. 9th at 7.30 A.M. 0·5 c.c., 0·2 c.c., and 0·1 c.c. were added to liquefied gelatin and plated; 0·5 c.c. of the sample was also treated by the method of Pakes for the detection of the coli group. On Sept. 10th 0·5 c.c. and 0·2 c.c. were entirely liquefied, and in 0·1 c.c. the colonies were so close as to be almost uncountable; from enumerations of portions of the plate more than 15,000 were estimated to be present per c.c. The portion of the sample treated by Pakes's method and subsequently plated gave flat, thin, greyish-white colonies with irregular edges. The organism thus isolated is slightly motile, does not stain by Gram's method, gives a large quantity of gas, does not liquefy gelatin, and produces acid. It is therefore referable to the coli group.

Sample 2, taken on Sept. 11th at 12 noon. 0·1 c.c., 0·1 c.c., and 0·05 c.c. were added to liquefied gelatin and plated. On Sept. 13th 0·1 c.c. and 0·1 c.c. were liquefied. 0·05 c.c. = 100 colonies—i.e., an estimation of 2000 per c.c.

Sample 3, taken on Sept. 12th at 2 P.M. 0·05 c.c., 0·01 c.c., and 0·1 c.c. were added to liquefied gelatin and plated. On Sept. 14th the colonies were enumerated as follows: 0·01 c.c., 4; 0·05 c.c., 20; and 0·1 c.c., 42; total 66 = 412 per c.c.

Sample 4, taken on Sept. 14th at 8.30 A.M 0·1 c.c., 0·1 c.c., and 0·1 c.c. were added to liquefied gelatin and plated. On Sept. 16th the colonies were enumerated as follows: 0·1 c.c., 20; 0·1 c.c., 23; and 0·1 c.c., 19; total 62 = 200 per c.c.

Sample 5, taken on Sept. 19th, at 8.15 A.M. 0·2 c.c., 0·1 c.c., and 0·1 c.c. were added to liquefied gelatin and plated. On Sept. 21st the colonies were enumerated as follows: 0·2 c.c., 80; 0·1 c.c., 40; and 0·1 c.c., 50; total 170 = 475 per c.c.

I therefore claim from the foregoing that (1) the number of organisms present per c.c. is a constantly variable quantity and may vary from 15,000 to 200 in a few days, a fact pointed out by other observers; (2) that on one occasion at least—e.g., Sept. 9th—the numbers were abnormally high; and (3) that on one occasion—Sept. 9th—organisms of the coli group were present in 0·5 c.c. of water.

I am, Sirs, yours truly,

KENNETH W. GOADBY.

Bacteriological Laboratory, Guy's Hospital, Sept. 28th.

"ITALY AND POLITICAL ASSASSINATION."

To the Editors of THE LANCET.

SIRS,—In your excellent leading article on the above subject there is one statement which in fair criticism, and I am sure you do not object to such, I must protest against with all my heart and soul and strength and mind, as it is contrary to fact, insulting (no doubt unintentional) to every loyal Roman Catholic, and a libel upon his Church. These are the words I object to: "Given the much-abused resource of the confessional, which whitewashes crime and rehabilitates the criminal on easy terms." This is one of the "conditions" from which you drew the inference that Italy is Senior Wrangler in, and is the nursery of, political assassination. To speak of the Sacrament of Penance whitewashing crime, &c., could only be a delusion on the part of those who had no knowledge of it. I take it for granted, Sirs, that in the opinion of every unprejudiced English judge or gentleman your Catholic readers and subscribers can speak the truth and are as worthy of belief in matters of fact as are any of their Protestant *confrères*, and I am sure they would repudiate your postulate as too absurd for Continental consumption and if uttered by an apostate of their own Church as blasphemous. Roman Catholics are in a minority in this country, Sirs, but minorities have rights, and when such a widely-read and excellent journal as THE LANCET traduces and insults their holy religion, whilst in the next breath it blesses and curses everything that they bless and curse, it is time for them to rub their eyes and protest against this want of proper accommodation and insular view of Peter and his keys. Sirs, if I have in any measure lifted the veil from your congenital myopia as regards the Sacrament of Penance, against which the gates of anarchy have never prevailed and never will prevail, God be thanked. The first step to anarchy, and the final loss of the Image of God and the gain of the stamp of hell, is due to the abandonment of the Sacrament of Penance by the anarchist. He has not even the remorse of Judas. Is he mad? Probably he is. Italy is reaping the whirlwind of her persecution of the Church and the Pope. Her anarchists as well as those of Spain find refuge in England. The right of asylum, except it be a lunatic one, to such outlaws is not fair to other nations. We may have to do penance for it yet.

I am, Sirs, yours faithfully,

R. G. MCCALMAN, M.D., C.M. Aberd.

Coldharbour-lane, S.E., Sept. 22nd, 1898.

*** We print the above letter, but our correspondent should understand that THE LANCET is a purely professional journal which does not interfere in questions of faith or general politics. The reflection was intended to apply to unworthy members of the Roman Catholic Church who abuse the rites of that communion.—ED. L.

ROYAL MASONIC INSTITUTION FOR GIRLS.

To the Editors of THE LANCET.

SIRS,—As candidates for the election of Oct. 13th I notice the names of two daughters of deceased surgeons and of one daughter of a deceased hospital steward. Many medical brethren would doubtless wish to support them. If any Masons care to send me their balloting papers duly signed I shall be pleased to divide the votes equally between the three candidates in question and so avoid waste.

I am, Sirs, yours faithfully,

F. TAYLOR SIMSON, Past Master.

Craven House, Northumberland-avenue, W.C., Sept. 26th, 1898.

UPLAND VILLAGE WATER-SUPPLIES.

To the Editors of THE LANCET.

SIRS,—Will your readers who reside in our large towns credit the following? The parish of Southstoke-cum-Woodcote, with a population of about 700, is situated partly

Digitized by Google

on the banks of the Thames and partly on the Chiltern Hills in Oxfordshire. The Woodcote division, with a population of between 200 and 300 souls, lies about 400 ft. above and 3 miles away from the river. The cottagers depend for water upon the drippings from their thatched or tiled roofs and upon roadside ponds filled in winter by the washings from the fields and from the highway. At the present time both ponds and tanks are absolutely dry and water has to be fetched from the river or from lowland wells, involving daily journeys of from six to eight miles. A deep well might be bored, from which an ample supply could be secured, but this has been opposed partly on the ground of expense and partly on the plea that the existing sources have been "satisfactory" for many years and that no excessive amount of disease has prevailed.

The inhabitants can see no objection to the use of roadside pond water for drinking purposes, but now that the ponds are absolutely dry they are inclined to consider the matter. But they are by no means unanimous as to discarding their beloved ponds and substituting a deep well instead.

In my opinion surface drainage from cultivated fields and high roads must always be a dangerous source from which to obtain drinking-water, but it would be of interest to hear the opinions of men who have given special attention to the question of water-supplies. It is stated that the medical officers of health in various districts similar in situation and water-supply to our own do not consider it imperative to condemn the roadside pond. Should you be able to insert this communication possibly some useful replies may be forthcoming. I am, Sirs, yours faithfully,

CHARLES REINHARDT, M.D. Brux., L.S.A. Lond.

Southstoke, Oxon., Sept. 27th, 1898.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Further Abandonment of Restrictive Plague Measures.—Comparative Mortality of the Diseases causing most Deaths.—Future Plague Policy.—Antitoxin Serum.—The Sanitary Commissioner's Report.

THE station master at Poona has received orders, to date from Sept. 7th, not to issue a ticket to any person without the production of a pass from the plague authority. This edict is to apply without distinction to all, Europeans and natives alike. Considering that there is no indigenous plague in Poona such an indiscriminate rule must only raise opposition to plague measures and, like dozens of other hard and fast regulations, will have to be modified sooner or later. I made the above note two days ago and now it is announced that the Bombay Government have decided to abandon the system of passes as well as that of detention camps. The detention camps were costly and unsatisfactory and the system of passes was almost unworkable. This action may be criticised on strictly sanitary grounds, but under all the circumstances it has become not only justifiable but imperative. The prospect of plague being among us for a number of years compels the abandonment of quarantine except for a limited period. Theoretical sanitarians imagined that the system would prove completely efficacious, but practically it has not been so and we are now confronted not only with a rising plague mortality, but with a reappearance and spread of the disease in various districts of the Mofussil.

At certain places a rigid medical inspection of travellers will be conducted. This will secure the obviously sick and the suspiciously sick and will doubtless deter all except the healthy from travelling. It is probable that the necessity for economy of expenses has determined this new policy. It was impossible that the previous rate of expenditure could last long. Every place was being ruined and the excessive inconvenience to which traders were subjected was more than desirable except for a temporary period.

Now that plague has come among us—and apparently to stay—it is interesting to note some of the figures in the Sanitary Commissioner's Report. What with plague, cholera, and famine the deaths in the Bombay Presidency for 1897 rose to 749,916, or 153,444 more than in 1896, giving a rate of 39·84 per mille, the decennial mean being 29·56. The birth-rate was low—33·46, there being 62,154 fewer births than in the previous year.

Cholera caused 57,109 deaths and plague 46,944. While deaths from plague in Bombay city are shown at only 10,237, the mortality of the year exceeded the quinquennial average by 22,666. Part of this excess was doubtless due to plague. It is to be observed that even then plague would not be shown to be more destructive than cholera. The deaths from dysentery and diarrhœa show an increase of no less than 49,920 over those of the previous year. But in India we deal with large figures. From its first appearance to the present time—a period of two years—plague has claimed over 100,000 victims, but cholera in 1896 alone caused 471,779 deaths, small-pox carried off 141,443 people, and "fevers" showed the enormous mortality of 4,578,944. Dysentery and diarrhœa are entered for 240,189 deaths, and while a separate return is not made for phthisis its prevalence and fatality are known to be extreme. The fear of plague may be over-estimated. Being strange to us and being attended with such a high mortality it created panic. We have come to regard cholera and consumption, fevers and dysentery, with such inevitableness that we fail to recognise that they are much more serious than plague. Then, again, there was the fear among sanitarians that plague would spread all over India. After two years it is still almost entirely confined to the Bombay Presidency. In the olden days, when nothing in the way of sanitation was in vogue, plague pursued its course unchecked; and from a study of outbreaks we find that it moved slowly—it spread slowly and while it frequently repeated itself in several places it did not extend over very large areas. The western part of India has always been chiefly attacked. It is reported that Dr. Simond, working with serum prepared by Dr. Roux at the Pasteur Institute, Paris, has obtained 47 per cent. of cures. It is stated, however, that no results have been obtained in the so-called pneumonic cases or in those cases where the generalisation of the microbe either in the lymphatic system or in the blood took place before the treatment. Under these circumstances I do not consider the result satisfactory because in hospitals 50 per cent. die within forty-eight hours, and of those who live over three days 50 per cent. recover. I am unable to report any further progress in the treatment of plague from any other quarter. Prophylactic inoculation is practically at a standstill both in Bombay and Calcutta.

Sept. 9th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The New Thompson-Yates Laboratories of Physiology and Pathology in University College, Liverpool.

THE development of the Liverpool Medical School has steadily progressed since its establishment in 1834. On the foundation of University College, Liverpool, in 1881, the Royal Infirmary School of Medicine (as the medical school was then termed) was incorporated with that body, becoming its medical faculty. In 1884 University College became an integral part of the Victoria University as one of its affiliated colleges, and since that time the history of the medical faculty has been one of continued success. The endowments of the chairs of anatomy, physiology, and pathology, were quickly followed by the gifts of the Tate Library, the Gossage chemical laboratories and Ashton Hall, the gift of the late Mr. George Holt, which that gentleman fully equipped for the use of the pathological department pending its removal to larger premises, and which in future will be known as the School of Hygiene, and, lastly, came the new laboratories of physiology and pathology, the noble gift of the Rev. S. A. Thompson-Yates, which are to be opened by Lord Lister on Oct. 8th. All these improvements show the great strides made in Liverpool in recent years in the direction of the advancement of medicine and its collateral sciences. The Thompson-Yates laboratories are located in a handsome building within the precincts of the grounds of University College. There is a spacious entrance-hall with tiled pillars extending all the way up the main staircase, a basement, ground floor, first and second floors and three mezzanines adjoining the main staircase. The ground floor is L-shaped, with the object of admitting a greater amount of window space than could be obtained by a rectangular form of building. This floor will be devoted to the department of pathology, and it contains the morbid histology class-room, 56 ft. in length by 26 ft. in breadth, to accommodate sixty students. This room opens at one end into the

Digitized by Google

pathological museum which has been considerably enlarged. In another part of the ground-floor is the bacteriological room, 53 ft. in length by 19 ft. in breadth; the benches in this room are covered with opaline tops as a sanitary precaution against the absorption of infective materials. Close by are rooms for pathological chemistry, pathological private research, a constant-temperature room for experimental pathology, and a room for photography. The large theatre is situated on the first floor and will accommodate 180 students. In winter the theatre will be devoted to physiology and in summer to pathology. The arrangements in the theatre are simply admirable. There is a liberal supply of electric lights, an interesting feature of which is an adjustable horizontal aerial bar which can be tilted round in any direction so as to bring the light to bear on any requisite object. There is also a switch at the back of the theatre for use with an arc lamp. On this floor is also situated the large physiological chemical laboratory, the best lighted room in a well-lighted building. Close by are the preparation, the research, and the electrical rooms. There is a large room for classes in recording drum work, each student in which will be provided with one of Professor Sherrington's drums. The histology class-room on the second floor is 60 ft. by 40 ft. and will accommodate 80 students, each of whom will be supplied with his own gas, water, electric light and microscope. This room is well lighted, and there is also an aquarium at one end. The north wing on the top floor contains the small animal room (the windows of which are guarded by wire cages), the preparation room, a combustion room, and a photograph room. The basement contains a cold storage room kept cool by the ammonia process, also a laboratory for the work of the clinical investigation society, and other rooms for experimental work. There is also on the basement a student's common room which can be altered in such a manner as to meet the purposes of a debating society. The laboratories are splendidly equipped all through and will afford every opportunity for the study of modern research. It is possible to say that the Thompson-Yates Laboratories of Physiology and Pathology in University College, Liverpool, are certainly equal to, if they are not superior to, any other institution of the kind in the kingdom and that they cannot be surpassed either here or on the Continent. Liverpool in particular and the community in general are much indebted to the noble generosity of the Rev. S. A. Thompson-Yates for the gift of this valuable building and its equipments, upon which he has expended the large sum of £35,000. The architect is Mr. A. Waterhouse, R.A., of London, who also designed the Liverpool Royal Infirmary.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Belfast Drainage System.

AT a joint meeting of the Improvement and Public Health Committees of the Belfast City Council held on Sept. 20th it was decided that a systematic test of all the drains should be made and that a weekly return of the drains so tested should be made to the two committees. I am afraid that unless a very large staff is appointed this will take a long time to accomplish. The addition of from three to six additional inspectors as proposed in order to efficiently carry out the work is not by any means sufficient. The following returns brought before the Improvement and Public Health Committees on the same date show a deplorable laxity in the prevention of insanitary defects. It appears that 4279 new houses were built during the past two years and of these only 1279 had the drains tested by water or smoke, while 3000 houses, although passed, have not had the drains tested. I trust that the corporation at its meeting on Oct. 1st will confirm this resolution passed at the combined meeting of the Public Health and Improvement Committees, insisting on the systematic and thorough testing of all the drains of houses in Belfast.

The Belfast Guardians and the Medical Profession.

Dr. E. C. Bigger having made a satisfactory report to the guardians of Belfast in reference to the treatment of fever patients in their hospital, in which he dispelled the impression conveyed in one of the papers that patients sent into the Union Fever Hospital and certified to be suffering from fever, but in whose cases the diagnosis may be wrong, are exposed to infection by being placed in a ward where other patients are so suffering, a most extraordinary discussion followed, in which some members of this truly remarkable board surpassed themselves in the violence of their attack on the medical profession. One guardian said he would suggest that Dr. Bigger should separate these classes in his list—the typhus fever cases, the typhoid fever cases, and those who were sent in for the purpose of getting the medical men the half-crowns. He also said that the "iniquitous system" (money paid for the notification of infectious diseases) was a "perfect swindle," while another guardian said that the medical men outside (in the city) were reaping a perfect harvest (i.e., notifying cases), and he added, "the doctors were great scoundrels"; and on being mildly asked by a medical guardian to withdraw that expression he boldly replied, "I'll withdraw nothing." One of these gentlemen who attacked the medical profession is reported in the public press to have remarked, in reference to an article which appeared in a Belfast newspaper dealing with the workhouse graveyard, that knowing the ground well "he would say there was just a sufficient ground of truth in the article to keep him from calling it a d——d lie from beginning to end." Truly, the Belfast guardians form a wonderful board!

The Health of Belfast.

For the week ended Sept. 17th the death-rate from all causes in Belfast was 30·6 and from the principal zymotic diseases 12·2. There were 247 cases of typhoid fever notified during the week, or 23 less than the previous week, and 341 less than the week before that. For the same week it appears from the Registrar-General's table that the total births and the total deaths in Belfast were the same—179. These figures, I regret to say, show an extremely bad state of affairs, for although, as compared with the previous week, there were fewer cases of typhoid fever notified (247 as against 270), the general death-rate has gone up from 27·9 to 30·6, and the mortality from zymotic disease has increased from 10·8 per 1000 to 12·2, which is really appalling. At the present time Dr. Lorrain Smith is making a most careful bacteriological examination of the water-supply of Belfast to see if it has any bearing on the typhoid fever epidemic, but up to the present no definite results have been announced. It is interesting to note that in the present outbreak of typhoid fever in Belfast Widal's reaction has in many cases failed, and in some of the fatal cases in whom during life Widal's test could not be obtained the spleen removed at the post-mortem examination has been subsequently found to teem with bacilli. This most interesting scientific observation would seem to confirm similar results observed in reference to certain recent outbreaks of enteric fever in England.

Ballycastle Sanitary Officer.

At a meeting of the Ballycastle Board of Guardians, held on Sept. 24th, Mr. Ewing was elected consulting sanitary officer.

Lunacy in Ireland.

It would appear from the forty-seventh report of the inspectors of lunacy in Ireland that lunacy there, as in England and Wales, is on the increase. On Jan. 1st the number of persons known to be insane in Ireland was 19,588, as against 18,966 in 1897. They were distributed as follows: 14,598 are detained in the district or county asylums; 170 in the Central Asylum, Dundrum; 691 in private asylums at the expense of relatives; 4030 in the workhouses; only 3 in prisons; and there were 96 single Chancery patients in unlicensed houses.

Sept. 28th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Diagnosis of a Bullet in the Subhyoid Region by Means of the X Rays.

M. CHOISEUL read a paper before the Academy of Medicine on Sept. 20th in reference to a case reported by Surgeon-Major Boisson and Surgeon-Major Mercus. The patient was a soldier who during an hysterical attack shot himself in presence of his family with a revolver

Digitized by Google

of 7 mm. calibre. The wound was in the neck. Hemiplegia followed together with constant pain in the subhyoid region which was increased by any attempt to swallow. Four weeks later he was seen by Surgeon-Major Boisson and Surgeon-Major Mercus. The scar was plainly visible but palpation gave no sign of the whereabouts of the bullet, so recourse was had to the x rays. Two skiagrams, taken respectively from the right and left sides, revealed a dark well-defined shadow situated at a point marked by a line joining the middle of the inferior border of the lower maxilla to the body of the hyoid bone and about one centimetre above the upper border of this latter. It was also evident that the foreign body was close to the skin upon the left side and thanks to these indications it was easily removed. The tissues were divided layer by layer until the hyoglossus was reached, when the bullet was seen and easily extracted. It weighed 3 grammes and was only slightly out of shape. The after progress of the case was uneventful and appropriate mental treatment entirely did away with the hysterical hemiplegia which had affected the patient since the accident.

The Abortive Treatment of Gonorrhœa.

At the same meeting of the Academy of Medicine M. Chauvel read sundry papers which had been sent in for the *prix Herpin* with reference to the abortive treatment of gonorrhœa. He came to the conclusion that these papers showed that there was no such thing as a really efficacious abortive treatment.

Mutiny at the Bicêtre Hospital.

On Sept. 24th 20 young patients at the Bicêtre Hospital, who were epileptic and were working in the locksmith's shop, broke out into open revolt. They all met contrary to the regulations, which prohibit any patient going into the shop except during working hours. When the attendants told them to go they refused and having armed themselves with the various iron implements which were lying about drove out the attendants and barricaded themselves in the shop. The chief of the hospital then sent for the firemen and the rebels, soaked with water, were easily disarmed by the attendants, who got in through the windows. The two ringleaders were handed over to the police.

The Cinematograph at the Faculty of Medicine.

M. Tuffier, Professor of the Faculty of Medicine and surgeon to the hospitals, has been using the cinematograph after the manner of Dr. Doyen to show the various phases of a surgical operation at his lectures. The photographs were all taken from the cases of M. Tuffier at the Pitié and the practical school of the faculty and the results were excellent.

An Ingenious Quack.

A most ingenious quack who was in the habit of "practising" with great success on board the boats running between Dover and Calais, has just been arrested in Paris. His method was as follows. He embarked on board the boat and during the crossing a woman, his accomplice, pretended to be violently seasick, so bad, indeed, that she collected around her a group of sympathising passengers. The swindler then turned up with a small bottle containing, as he affirmed, a drug of marvellous efficacy, which he offered to the sick lady. She having swallowed one mouthful declared herself miraculously restored. The bystanders never failed to ask the quack for his secret, and he, giving himself out as an inventor who was going to England to dispose of his patent, said that nevertheless for humanity's sake he would dispose of a few bottles of his medicine just before the boat arrived in port for the sum of 20 francs each. The silly people who bought them had thus no time to discover that the "drug" was only coloured water, an unlucky discovery reserved for their return voyage. This *chevalier d'industrie* was arrested while walking in Paris, where he was recognised by one of his dupes.

The Case of the Prince of Wales.

Dr. Lucas Championnière, the celebrated senior surgeon at the Beaujon Hospital and a member of the Academy of Medicine, has published in his paper, the *Journal de Médecine et de Chirurgies Pratiques*, under date August 10th, a noteworthy article entitled "The Prince of Wales and his Fractured Patella." He there states in bitter language that recent advances in surgery are not enough to make the medical attendants of the Prince undertake the responsibility of applying them in this case to a patient of such high degree whose successful treatment puts their reputation at stake. He is perfectly astonished that at the consultation in which Lord Lister himself took part the idea of operative interference was unanimously rejected, especially as the distance between the fragments was more than two inches. It is amazing that in the country of Lister, to whom is due the first idea of treating this form of fracture by direct suture, the Sovereign (*sic*) should not enjoy in the same degree as the least of his subjects the benefit of this admirable treatment—unless, indeed, there was something in the general health of the patient to contra-indicate any surgical operation whatever, and such contra-indication has never been hinted at. Dr. Championnière would without doubt have freely opened the joint and brought the bony fragments together by two stout sutures. He has himself treated 53 cases of fractured patella in this way, who have all recovered perfect use of their joints and are able to do the hardest work. Among these was an acrobat who two months after the operation used to perform in a circus *le saut périlleux*. Even elderly persons rapidly recovered after the operation. On the other hand, he has always seen immobilisation leave stiffness in the limb for the remainder of life as well as muscular atrophy and diminished physical activity, leading at a certain time of life to all those cardio-pulmonary and gastric complications which come from want of exercise. The article finishes in the following words: "These are the reasons why I consider, until more ample information is forthcoming, that one must regret that we have not seen this operation performed upon a prince who possesses the respectful sympathy of all Frenchmen, and whose proverbial activity is so desirable for all, and not merely in his own interests but those of humanity."

Sept. 27th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Coloured Race in Life Assurance.

THE Atlanta University has investigated the comparative mortality-rates of the negro race. In respect to phthisis and pneumonia the coloured population had a death-rate of 75·5, as compared with that of the white population, 32·8. In fevers, as typhoid, scarlet, malarial, &c., the excess was 30 per cent. on the same side; in cholera infantum, convulsions, &c., it was 165·1. As to phthisis the percentage of the excess of deaths per 10,000 in the case of blacks over the deaths of whites, covering periods of four years each, from 1881 to 1895, was from 143 to 172 in Atlanta, from 90 to 137 in Memphis, from 162 to 239 in Charleston, from 128 to 149 in Baltimore, and from 87 to 114 in Richmond. The Prudential Company has had experience in both equal and discriminated insurance for blacks and whites. For a term of years it has been in the habit of giving one-third less insurance for the same money to coloured than to white adults, from 12 to 70 years. During the period in question the mortality was separated and tabulated by colour and special study and search among health reports and census reports was made. From 1884 to 1893 inclusive the company's experience showed an average loss per $1000 at a risk of $16·96 among whites and $21·63 among blacks. The causes were found to be mainly: comparatively higher actual mortality resulting from lack of physical vigour, inherited tendencies to disease, neglect in sickness, improper food, unwholesome habits of life and unhealthy localities; a heavy lapse rate, in which the "selection" was against the company as usual; a low moral sense; and ignorance of its attendant evils, although the last-named cause might seem to be included in the others. Even among the small number of negroes who are thrifty, intelligent, and on a high comparative level of moral and social living, the Prudential Company is satisfied that mortality still exceeds that among whites, owing to low vitality and inherited weakness of constitution. The Sun Life Company has reported a similar experience and belief, adding that southern whites object to joining any company which accepts negro risks freely, not from race prejudice, but because they do not believe insurance of the two races on equal terms to be equitable.

The New York State Pathological Laboratory.

During the spring of 1898 the Legislature of the State of New York appropriated a sum of money to the purpose of equipping and maintaining a laboratory to be devoted to the study of the causes, mortality-rate, and treatment of cancer. This laboratory is now being conducted under the supervision of the medical department of the University of Buffalo. The laboratory is equipped with every possible facility for investigating the disease, both in its clinical and pathological aspects. The officers of the institution invite correspondence with physicians throughout the country in regard to statistics and all matters connected with this study; they also desire to secure reprints of all monographs pertaining to this subject for its library. They furthermore particularly wish to learn the names and addresses of the various quacks, charlatans, and institutions advertising as curing this disease, as well as the methods in use amongst them. Such correspondence will be regarded as absolutely confidential if so requested. It is desired also to secure specimens of tumours from all varieties of the lower animals, either gross specimens or fragments for microscopical examination. These should be sent securely packed, the former immersed in weak alcohol or formaline solution, the latter in pure alcohol. They will be gratefully acknowledged or even paid for in exceptional cases.

Medical Department of Cornell University.

Through the munificent gift of $1,500,000 arrangements have been perfected by which Cornell University is to establish a medical department in the City of New York. The donor is Colonel Oliver H. Payne, formerly a member of the board of trustees of the New York University. The condition which has made the establishment of this new college possible arose from the controversy which raged a year ago in the Council of the University of the City of New York over the treatment of its medical department, which led to the withdrawal not only of almost the entire medical staff but also of nearly half of the active members of the council, of whom Colonel Payne was one. The faculty of the new college includes the entire governing faculty and most of the instructors and professors of special branches lately connected with the University of the City of New York and also several of those associated with the Bellevue Hospital Medical College. The full four years' course of the Cornell University Medical College is given in the City of New York and the course of the first two years is also given in Ithaca, where the University is located. As co-education of the sexes is allowed in Cornell University, the following provision has been made. Men students may take half the course in Ithaca and the other half in New York; women students must take the first half of the course in Ithaca (where a home is provided in the Sage College for Women) and the latter half in New York. The proposed Cornell Medical College will be situated on the block bounded by Twenty-seventh- and Twenty-eighth-streets and First-avenue. It will be an imposing building 200 ft. by 100 ft., five stories high and some 85 ft. to the cornice. The interior of the building will be simple and severe in character, but the materials used will be those specially fitted to the purposes of a medical college, glazed brick and tile predominating in the finish of the different rooms. The ground floor will be partly occupied by the dispensary, which forms a complete and separate department, with general waiting-rooms for males and females, small theatres for operation and separate rooms for the eye, ear, nose, and throat departments, for the apothecary, &c. The second floor contains the rooms for the skin, gynæcological, and orthopædic departments, and orthopædic workshop, and two section demonstration theatres. The third floor will contain physiology students' and private laboratories, chemistry students' and private laboratories, recitation rooms, amphitheatres, and private rooms for professors. The fourth floor will contain the workshop, museum, dark room for preparing and mounting specimens, manikin room, materia medica laboratory, bacteriology laboratory, room for operative surgery, lavatories, &c. The fifth floor will contain the dissecting rooms for male and female students.

Sept. 19th.

BRISTOL ROYAL INFIRMARY.—An anonymous donor has promised £1000 if twelve others will give a similar amount towards the liquidation of the debt of £13,000 owing by the Bristol Royal Infirmary.

THE INDIAN MEDICAL ASSOCIATION AND REFORM IN MEDICAL EDUCATION.

IN May, 1898, the Council of the Indian Medical Association decided upon sending to the Government of India a memorandum as to reform in medical education. The points which the Council wished chiefly to lay stress upon were as follows:—

1. A unified standard of preliminary examination in general education for admission to medical study for all universities in India. As the F.A. of Calcutta and the Intermediate of Lahore are already accepted by two universities the other academical bodies should be asked to raise their preliminary education standard to this level.
2. That the medical degrees granted by Indian Universities be of one standard and one nomenclature—namely:
   (*a*) Licentiate of Medicine and Surgery or L.M.S.
   (*b*) Bachelor of Medicine or M.B.
   (*c*) Master of Surgery or C.M.
   (*d*) Doctor of Medicine or M.D.
   No imitations of these degrees should be permitted.
3. A unified standard of preliminary examination (the Entrance or Matriculation of Indian Universities or the High School Certificate) a full curriculum (5 years), and a unified diploma (Diplomate in Medicine, Surgery, and Midwifery, or D.M.S.M.) for all Military Assistant Surgeons.
4. A unified standard of preliminary examination (the Middle School Examination of the Government European Code of its equivalent entrance), a curriculum of four years' medical study, and a unified professional examination and certificate of qualification for all hospital assistants, whether civil or military, and for all junior medical schools, whether State or private. Certificate in Medicine, Surgery, and Midwifery (C.M.S.M.).
5. The formation of a General Medical Council for India (with powers similar to the General Medical Council of Great Britain) composed of an equal proportion of Government officials and independent medical practitioners.

The memorandum, which was drawn up by the secretary of the association, Dr. James R. Wallace, also remarked upon the fact that in India almost everything was in the hands of the Government and that therefore it was the duty of the Government to see that medical education was kept at a high level, whereas it was willing "to accept anything in the shape of a 'diploma' as good enough for its own local services and for the medical requirements of the public." It also deals with the licences in Medicine and Surgery granted under the auspices of the Dufferin Fund and says that the question must be raised as to the legality of these licences.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON. — In September the following candidates passed in the subjects indicated:—

Surgery.—G. H. Bedford (Section I.) and F. P. Bush, Guy's Hospital; H. H. Cotman (Section I.), Aberdeen and London Hospital; H. L. Heath (Section II.), Toronto and Cambridge; J. W. King (Sections I. and II.), Charing Cross Hospital; E. C. Scarlett (Section I.), Royal Free Hospital; and A. E. Shaw, Cambridge and St. Thomas's Hospital.

Medicine.—C. G. Catterall (Section I.), Leeds and Westminster Hospital; H. Cooper, Aberdeen; H. H. Cotman (Section I.), Aberdeen and London Hospital; H. L. Heath (Section II.), Toronto and Cambridge; and W. M. Hocken, Liverpool.

Forensic Medicine.—C. G. Catterall, Leeds and Westminster Hospital; and W. M. Hocken, Liverpool.

Midwifery.—C. G. Catterall, Leeds and Westminster Hospital; H. H. Cotman, Aberdeen and London Hospital; E. L. D. Dewdney, King's College Hospital; L. Liebster, Vienna; and A. H. Safford, King's College Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—H. L. Heath and J. W. King.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the third examination for the degree of Bachelor in Medicine, held at the College of Medicine, Newcastle-upon-Tyne, in September, the following candidates satisfied the examiners:—

Second-class Honours.—James Robert Burn, Frederic William Lambelle, Richard Henry Dix, Thomas Smirk Percival Parkinson, and Robert Peart, College of Medicine, Newcastle-upon-Tyne.

Pass List.—Reginald Alderson, College of Medicine, Newcastle-upon-Tyne; Clifford Harold Brookes, St. George's Hospital; Henry Eggleston and Joseph James French, College of Medicine, Newcastle-upon-Tyne; Duncan Matheson Johnston, St. Bartholomew's Hospital; Fred Stuart, College of Medicine, Newcastle-upon-Tyne; Eleanor Shepheard, London School of Medicine for Women; William Johnston Symes, Sheffield School of Medicine; Leonard Satchwell Smith, Mason College, Birmingham; and Ralph Harry Vincent and Edgar Sheldon Wilkinson, St. Bartholomew's Hospital.

THE REGISTRATION OF PLUMBERS AND DOMESTIC SANITATION.—The Lord Mayor of Manchester presided at a public meeting in Manchester on Sept. 19th, at which Dr. Mansel-Howe delivered an address on "The Registration of Plumbers and Domestic Sanitation." We must, he said, feel sure that it was upon the efficiency of a system ensuring the qualification of plumbers and enabling the public to recognise the qualified man that sanitary plumbing actually depended. The registration of the plumber deserved to come under the recognition and the protection of Parliament. Mr. Lees Knowles, M.P., said that all parties in the House of Commons were committed to the principle of the Bill, the main object of which was to afford additional safeguards to the public health by enabling persons employing plumbers to select, when they desired to do so, those who had given evidence of their qualification for plumbers' work.

PRESENTATIONS TO MEDICAL MEN.—At a well-attended public meeting of subscribers held on Sept. 16th in the Council Chamber, Banff, Mr. George Wilson, M.B., C.M. Aberd., of that town, was presented with a gold watch and chain and a purse of sovereigns on his leaving the district. The inscription on the watch is as follows: "Presented to Dr. George Wilson, along with gold albert and purse of sovereigns, on the occasion of his leaving Banff, by friends and well-wishers in Banff and district. Sept. 16th, 1898." On the front of the watch there is engraved the monogram of the recipient. It may also be mentioned that Dr. Wilson was subsequently the recipient of a valuable study chair, bearing an appropriate inscription, from the superintendent and officials of the Ladybridge Asylum.—Mr. Reginald Wade, M.R.C.S. Eng., L.S.A., of Highbridge, Somerset, has been presented with an ink-stand, suitably engraved, by the members of the class of the St. John Ambulance Association consisting of employés of the Great Western Railway Company in appreciation of his services as honorary lecturer.—On Sept. 21st the children of the Chulmleigh (North Devon) Board Schools presented the chairman, Mr. Joseph Tucker, M.R.C.S. Eng., L.S.A., with a silver water-jug as a mark of respect and esteem on the occasion of his marriage. The Chulmleigh Cricket Club presented him with a toilet set and the children of Week School with a biscuit box. Lieutenant Gibson, on behalf of the G Company of Devon Volunteers, gave an address and a case of silver dessert knives and forks. Mr. Tucker was largely instrumental in establishing at Chulmleigh the G Company Volunteers of which he is the Lieutenant in command.

DIPHTHERIA IN LONDON.—Diphtheria in London has been a diminishing quantity during many weeks past, as shown by successive four-weekly periods, both as regards amount of disease and recorded numbers of fatal cases. In the four weeks ended on July 16th there were notified 849 attacks in London, all the several sanitary districts having been invaded, five of them having an aggregate of 290 cases, while five other areas had only 9 cases in all. The weekly average of attacks was 212, that of registered deaths was 29, the total being 116. The resulting case mortality was 13·7 per cent. In the four weeks next succeeding the total number of notified cases fell to 785, giving a weekly average of 196, and two sanitary districts escaped invasion. Only one district had more than 50 attacks notified, while in five other areas only 12 cases were heard of. The registered deaths fell to 96, a weekly average of 24, and the case mortality also fell to 12·2 per cent. The next similar period, ended on Sept. 10th, revealed a still further decline of attacks, the total having been 699, a weekly average of 175 being the result. All the sanitary districts were invaded, but not one had as many as 50 cases, whilst five areas had only single attacks recorded. The registered deaths, however, increased to 107, or 27 weekly, and the case mortality became 15·3 per cent. In the Outer Circle the course of fatal diphtheria has been erratic, the figures for the several weeks of the three periods dealt with having been 11, 11, 10, and 9 in the July period, or 41 in all; 11, 11, 15, 8, and 13, or 47 in all, in the August period, and 13, 9, 7, and 10, or 39 in all, in the period ended on Sept. 10th. In each of the two complete weeks which have since elapsed the registered deaths from diphtheria in London have been identical in number—namely, 29. But while the corrected decennial average was exceeded by 13 in the earlier of those weeks that average was exceeded by as many as 18 last week. In the Outer Circle there were 11 recorded deaths in the earlier week and 12 last week. Of the 23 deaths thus registered 14 belonged to the West Ham district.

ICE-CREAMS.—On Sept. 19th a man was fined 30*s.* for manufacturing ice-cream amidst dirty surroundings at Port Talbot, South Wales.

TYPHOID FEVER AT HONICKNOWLE.—At the meeting of the Plympton Rural District Council, held on Sept. 23rd, Mr. Noy Scott, the medical officer of health, reported that typhoid fever had broken out in the hamlet of Honicknowle, in the parish of St. Budeaux. There are at present 23 cases of the disease in the village, which has 506 inhabitants and 106 houses. He attributed the outbreak to the insanitary and offensive condition of the main sewer, the pollution of the stream, and minor insanitary matters in the houses.

ABERDEEN CORPORATION LODGING-HOUSE.—This establishment, which will assist materially in the solution of the problem of house accommodation for the poorer classes, is almost finished. It will be opened probably in November next. The charges per cubicle have been fixed at rates varying from 6*d.* to 4*d.* per night and the manager to be appointed will have a salary of £80 per annum, with residence, fire, and light. There will also be an assistant manager, a cook, a laundrymaid, and six other servants for cleaning the dormitories, &c.

LITERARY INTELLIGENCE. — MESSRS. J. & A. Churchill's announcements for October include the following new books and new editions:—A Manual of Ophthalmic Surgery and Medicine, by Mr. Walter H. H. Jessop, ophthalmic surgeon to St. Bartholomew's Hospital. The work contains over 100 illustrations, 5 coloured plates, and test types. A second revised and enlarged edition of Morris's Anatomy, with 800 illustrations, of which 200 are new or altered. The fifth edition of Taylor's Practice of Medicine, revised throughout with improvements in size and type. The fifth edition of Clouston's Clinical Lectures on Mental Diseases. A new work on Diet and Food considered in relation to Strength and Power of Endurance, Training and Athletics, by Dr. Alexander Haig, physician to the Metropolitan Hospital. A Synopsis of Surgery, by Mr. R. F. Tobin, surgeon to St. Vincent's Hospital, Dublin. A Textbook of Histology, including the Microscopic Technic, by Dr. Philipp Stöhr, Professor of Anatomy at the University of Würzburg, and edited by Dr. Alfred Schaper, demonstrator of histology at the Harvard Medical School. The sixth edition of Goodhart's Diseases of Children. Vol. iv., and reprints of vols. i., ii., and iii., part 1, of Allen's Commercial Organic Analysis. Vitality: an Appeal, an Apology, and a Challenge, by Dr. Lionel Beale, Emeritus Professor of Medicine in King's College.—We notice in connexion with Mr. John Poland's forthcoming work upon "Traumatic Separation of the Epiphyses" that Messrs. Smith, Elder and Co. are about to publish a Skiagraphic Atlas by the same author. It illustrates the development of the bones of the wrist and hand as displayed by the Roentgen rays. This is the first instance in which a series of skiagrams showing the ossification of the bones of these parts has been traced over a period of years from early infancy. Such an atlas may well be of great practical use to the surgeon and student.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ALFORD, H. J. MARMADUKE, L.R.C.P. Lond., M.R.C.S., has been appointed Resident Dispensary Medical Officer to the Weston-super-Mare Hospital.

BAILEY, MATTHIAS, M.R.C.S., L.R.C.P., has been appointed Senior House Surgeon to the Bootle Borough Hospital.

BOULTON, A., L.R.C.P. Lond., M.R.C.S. Eng., D.P.H., has been re-appointed Medical Officer of Health by the Horncastle Rural District Council.

BUIST, R. C., M.D., C.M. Edin., has been appointed a Medical Officer in the department of Gynæcology for the new Hospital for Women in connection with the Dundee Royal Infirmary.

Digitized by Google

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898, bound in cloth, gilt lettered, price 18*s.*, carriage extra; and Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*, can be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

THE MUNYON CASE.

ON Sept. 23rd at the London County Sessions, James Edward Deane, forty-four years, described as a medical practitioner, surrendered to an indictment charging him with stealing three small sums of money—3*s.*, 3*s.*, and 4*s.*—belonging to his master, James Monroe Munyon, of "Munyon's Homœopathic Remedies," 121 and 123, Shaftesbury-avenue. It was alleged that the accused whilst employed as a "consulting physician" at the establishment named, sold "cures" taken from the stock efore they were stamped and in some cases failed to acco for the money. The London manager for Munyon said his employer engaged "Doctor" Deane. The accused was under him and commenced with a weekly wage of £4, increased subsequently first to £5 and then to £6. In cross-examination he stated that Munyon had an honorary degree from the University of Tennessee. He (witness) repudiated the suggestion that it was not possible to get a qualified man to occupy the position of manager. He could get half a dozen reputable doctors. For the defence it was submitted that Munyon instructed Deane to act as he thought best and to recoup himself out of the sales for any expense he was put to in his position. The jury returned a verdict of "Not guilty."

FUCUS VESICULOSUS.

To the Editors of THE LANCET.

SIRS,—Would any of your readers who have had experience in its use give me information about fucus vesiculosus—whether it does really reduce fat and what its general action is? Are there any indications to guide its use? Has it any wasting effects on normal glands? I should be obliged by any information before prescribing it for general obesity.

I am, Sirs, your faithfully,

Sept. 27th, 1898. ENQUIRER.

A REVEALED CURE.

IN THE NAME OF ALLAH, THE MOST MERCIFUL AND THE MOST COMPASSIONATE.

A REVEALED CURE FOR THE BUBONIC PLAGUE.

UNDER the above stimulating heading a gentleman of Gurdaspur, Punjab, named Mirza Ghulam Ahmad, who places in brackets by the side of his name as an alternative title "The Promised Messiah," has published a little pamphlet explaining that Almighty God has been pleased to choose him as a medium through which to reveal "by direct inspiration" the specific remedy for the plague. The following are the words in which Mirza Ghulam Ahmad makes his revelation:—

> "The cure which I proclaim for the plague consists of two different medicines. One of them called the *Tiryaq-i-Ilahi* or the Divine treacle has been prepared solely by me, and it is to be taken as hereafter suggested. The other which is to be applied externally to the glands is an ointment called *Marham-i-Isa* or the ointment of Jesus. It would not be out of place to give a brief history of this wonderful ointment. It was originally made, about nineteen hundred years ago, after the crucifixion of Jesus Christ (peace be with him). It was prepared by the disciples of that prophet for applying it to the wounds on his hands and feet; and it turned out to be wonderfully efficacious in curing the said wounds within forty days. There is not the least doubt that Jesus did not die upon the cross. He had, however, received severe wounds which had rendered him so senseless when taken down, that he was generally believed to be dead. But it is a fact that the body was on account of the presence of the Sabbath taken down from the cross sooner than it was usual—so soon, indeed, that even Pilate marvelled if he (Jesus) were already dead, and moreover when one of the soldiers pierced his side with the spear, blood came out. These and such other circumstances go a long way to prove that Jesus came down alive from the cross. In short when this ointment, the *Marham-i-Isa*, had restored Jesus to complete health, he went out to preach the Gospel to those sects of the Jews that had scattered far and wide and had settled in other countries. It is for this reason that in Islamic Theological Literature Jesus is known under the name of *Masih*, a word which means one who travels much."

Then follows a lot of gibberish about the dosage of the "divine treacle," and at the end are placed half-a-dozen common-sense regulations as to domestic hygiene in the presence of infectious disease. The shrewdness which led Mirza Ghulam Ahmad to combine simple sanitary suggestions, bound to do good if followed, with the rhodomontade from which we have quoted leads us to suspect him of being a designing scamp and not merely a blasphemous idiot. We note that he is receiving subscriptions.

"INCARCERATION OF THE PENIS."

To the Editors of THE LANCET.

SIRS,—The account of the above in THE LANCET of July 23rd has its parallel in my own practice. A respectably dressed man, a widower, presented himself one morning evidently in great distress. His tale was that "the night before he had been larking and had passed his late wife's wedding ring over his penis." The ring, an unusually heavy one of the gipsy pattern, was seen tight up against the suspensory ligament of the urethra, the penis was swollen and œdematous, hanging below

Digitized by Google

like a big sausage, and the urine was dribbling away drop by drop. An attempt had been made with a file to remove the ring, but had evidently been soon abandoned as considerably more cuticle than gold had been removed by the process. I had in my tool chest a pair of sharp-cutting pincers such as are used for clipping through nails or wire. With these I cut through the massive ring and while one cut end impinged against the inner side of the blades which acted as a fulcrum I seized the other end with a strong pair of pliers, and opened out the ring which fell to the floor, much to the man's relief. As he did not turn up again I concluded that the penis soon resumed its normal appearance and functions.

I am, Sirs, yours faithfully,
Leicester, Sept. 26th, 1898. J. HEADLEY NEALE.

"THE MEDICAL DIRECTORY."

To the Editors of THE LANCET.

SIRS,—Your correspondent, "A Monmouthshire Subscriber of Thirty Years' Standing," thinks it a blemish that we include Monmouthshire in the Wales section. We agree with him that the position is anomalous, but the anomaly is due to the fact that we follow the example of Parliament, which has included the county of Monmouth in various statutes passed on behalf of the Principality. We may also refer as an example to the official title of the University College of South Wales *and Monmouthshire*.

We are, Sirs, yours faithfully,
J. & A. CHURCHILL.
Great Marlborough-street, W., Sept. 26th, 1898.

To the Editors of THE LANCET.

SIRS,—I am of opinion that an alphabetical list is after all the least troublesome. If you want to find the address of a man you have, with the present arrangement, to look through five or six different lists.

I am, Sirs, yours faithfully,
Cardiff, Sept. 26th, 1898. T. GARRETT HORDER.

DEVON COUNTY COUNCIL: MEDICAL EVIDENCE AT INQUESTS.

AT the meeting of the Devon County Council held on Sept. 22nd the Finance Committee reported that they had interviewed Mr. J. Tucker, M.R.C.S. Eng., L.S.A., of Chulmleigh, who had complained that the coroner for the Crediton district systematically omitted to call him to give evidence at inquests upon people whom he had attended. The committee had received a letter from the coroner explaining his conduct, and although they did not consider the Council had any jurisdiction in the matter, still the committee were of opinion that much stronger and more serious reasons than those given by the coroner were needed to justify his omission in the cases complained of to take the evidence of the medical attendant who was indicated by the Coroner's Act as generally the best and the proper witness to be summoned for the purpose. Sir John Phear, in moving the adoption of the report, said the explanation of the coroner was most remarkable, his excuse being that two years ago Mr. Tucker had passed a personal affront upon him which he visited upon the medical man by "boycotting" him and forbidding the deputy coroner to summon him, although the medical attendant was the proper person indicated by Act of Parliament to give evidence. After some discussion, during which Mr. Lambert, M.P., asked whether the County Council could not take some action in the matter, Lord Clinton, who presided, remarked that he thought sufficient had been said and the coroner would take this as a serious warning, adding that if the Council took any further action it would raise a very large question and after the strong remarks of the Finance Committee it would be well to let the matter remain where it stood. The report was then adopted.

"THE NATURE OF DRY-ROT."

To the Editors of THE LANCET.

SIRS,—Dry-rot is the cancer of buildings and can be successfully treated only by the treatment of cancer—total extirpation of the diseased structure. Dry-rot usually begins in wood, but it passes through brick with the greatest ease and less easily through porous stone. It cannot penetrate Portland cement. My house was badly affected some years ago and has been completely freed by the following measures: 1. Cut out and burn all affected woodwork, being careful to follow it into joists, lathing, wall-plates, plugs, &c. 2. Face all affected brickwork with Portland cement, carrying the cement a foot beyond the infected area. 3. As an additional precaution it is well to sluice the neighbouring woodwork for a couple of feet beyond the excised portion with saturated aqueous solution of corrosive sublimate. After this the fungus does not recur. After applying strong solution of chloride of zinc (Burnett's disinfecting fluid) the fungus does in time recur. To prevent recurrence it is well to attend to ventilation under floors and in other confined spaces.

I am, Sirs, yours faithfully,
Southend, Catford, S.E., Sept. 26th, 1898. CHARLES MERCIER.

M.D. Edin.—If the gentleman in question took the L.R.C.P. under the old regulations he possesses a registrable qualification. If, however, he took it under the new regulations—i.e., after the inception of the Conjoint Scheme—he is not fully qualified and therefore can only be employed as a pupil. Our correspondent had better apply to the General Medical Council.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat Hospital (2 P.M.).

TUESDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.), Royal Ear Hospital (3 P.M.).

WEDNESDAY (5th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

THURSDAY (6th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex, (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

FRIDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (8th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (5th).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Papers:—Dr. J. Walters and Mr. A. R. Walters: Case of Puerperal Septicæmia treated by Antistreptococcic Serum.—Dr. Cullingworth: Early Ectopic Gestation (? tubo-uterine) complicated by Fibro-myomata of the Uterus.

FRIDAY (7th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—Dr. S. D. Clippingdale: Some Considerations of the Life and Work of a General Practitioner (Presidential Opening Address).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

THURSDAY (6th).—LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical Demonstration to Senior Students.

During the week marked copies of the following newspapers have been received: *South Wales Daily News, Bramley Telegraph, Manchester Guardian, Leicester Post, Wolverhampton Chronicle, Worcester Echo, Devon Gazette, Cheltenham Examiner, Times of India, Pioneer Mail, Builder, Walsall Free Press, Sheffield Telegraph, Yarmouth Independent, Newcastle Chronicle, Dundee Advertiser, Yorkshire Post, Architect, Glasgow Herald, Berkhamsted Times, Midland Counties Express, Liverpool Daily Post, Derby Telegraph, Nottingham Express, Beverley Guardian, Brighton Gazette, Portsmouth Times, Essex Telegraph, Bristol Mercury, Hove Gazette, Cambridge Express, Bedford Mercury, Falkirk Herald, Scotsman, Western Mail, Birmingham Gazette, Leeds Mercury, East Anglian Daily Times, Blackpool Gazette, Newcastle Daily Leader, Sanitary Record, Local Government Chronicle, Reading Mercury, Mining Journal, Hertfordshire Mercury, City Press, St. Bartholomew's Hospital Journal, Oxford Times, Surrey Advertiser, Bolton Evening News, Local Government Journal, Weekly Free Press and Aberdeen Herald, Cork Examiner, Skibbereen Eagle, Warwick Times, Weekly Sun, Evesham Standard, Hull Times, Peterborough Standard, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Mr. R. E. Abbott, Portsmouth; Addenbrooke's Hospital, Cambridge, Secretary of; Messrs. Allen and Hanburys, Lond.; Apothecaries' Society, Lond., Secretary of; A. S. M.; A., Wisbech.

B.—Dr. J. S. Boden, Lond.; Mr. M. Bailey, Bootle; B., Bradford; Mr. F. Bochin, Lond.; Mr. L. A. Bidwell, Lond.; Mr. E. Bower, Birmingham; Mr. J. W. Bird, R.N., Devonport; Messrs. Burgoyne, Burbidges, and Co., Lond.; T. B. Browne, Ltd., Lond.; Mr. A. E. Barker, Lond.; Mr. S. T. Beckett, Cullingworth; Birmingham and Midland Ear and Throat Hospital, Secretary of; Messrs. Burroughs, Wellcome, and Co., Lond.; Professor Jules Brissonnet, Tours; Mr. Lennox Browne, Lond.; Messrs. Baillière, Tindall, and Cox, Lond.; Dr. E. C. Baker, Brighton; Sir Walter Besant, Lond.; Rev. R. A. Bull, Southborough; Bristol Infirmary, Secretary of; Mr. F. Bauermeister, Glasgow; Bootle Borough Hospital, Secretary of.

C.—Sir J. Crichton-Browne, Lond.; Colonial Office, Secretary of; Cortland Wagon Co., Lond.; Messrs. J. A. Carveth and Co., Toronto; Cork-street Hospital, Dublin, Lady Superintendent of; Mr. W. T. Councilman, Boston, U.S.A.; Messrs. Cassell and Co., Lond.; Dr. H. F. Call, Rimanski; Messrs. J. and A. Churchill, Lond.; Dr. W. H. Cooke, Bath; Dr. A. H. Croucher, Eastbourne; Dr. J. M. Clarke, Clifton; Cuc, Manchester; Dr. Macfie Campbell, Liverpool; Mr. W. J. Clay, Edinburgh; Cantab, Lond.; Mr. T. Cooke, Lond.

D.—Mr. A. Duke, Cheltenham; Douglas Borough, Town Clerk of; *Derbyshire Free Press*, Editor of.

E.—Messrs. Elliott, Son, and Boyton, Lond.; Dr. J. O. Eyre, Lond.

F.—Mr. Francis E. Freemantle, Ripon; Messrs. Fieber Bros., Lond.; Fairbairn, Ltd., Edinburgh; Dr. B. Fox, Bristol; Messrs. Fletcher, Fletcher, and Co., Lond.

G.—Mr. H. J. Glaisher, Lond.; Mr. F. Garrett, Armscote Manor; G.M.W.; *Guardian*, Lond., Editor of; Surg.-Gen. A. A. Gore, Simla.

H.—Dr. F. L. Hart, Lond.; Mr. J. Hutchinson, Lond.; Mr. C. W. C. Hyslop, Church Stretton; Mr. C. H. Harris, King's Heath; H., Bristol; H. M. B.; Hirschfield Bros., Lond.; Hastings Bros., Lond.; Mr. E. Huntley, Lond.; Mr. M. Houghton, Lond.; Mr. R. Harrison, Lond.; Mr. J. J. Harding, Ballincollig; Mr. Charles Hutley, Askew; Huddersfield, Mayor of; Messrs. J. Haddon and Co., Lond.; Mr. J. Heywood, Manchester.

J.—Dr. A. H. Jeremy, Southampton; J. D.; Messrs. T. B. Jones and Co., Leeds; Dr. J. Johnston, Bolton.

L.—Dr. J. Fletcher Little, Lond.; Dr. J. Lowe, Lond.; Mr. R. Lake, Lond.; L. M., Woodford Green; Messrs. Lee and Martin, Birmingham; Mr. G. J. R. Leeson, Lond.; Dr. A. Love, Drumquin, Ireland; Dr. J. H. Lamb, Crewkerne; Leeds Union, Secretary of.

M.—Dr. F. J. McCann, Lond.; Mr. J. S. McKendrick, Stonehaven; Metropolitan Machinists' Co., Lond.; Dr. Mansel-Howe, Manchester; Mr. R. J. Marshall, Lond.

N.—Dr. J. H. Nicoll, Glasgow; Messrs. Nicolay and Co., Lond.; National Society for Aid to the Sick and Wounded in War, Lond., Secretary of; National Provident Institution, Lond., Secretary of; North Riding Infirmary, Middlesbrough, Secretary of; Mr. C. A. Notley, Catford; Nursing Institute and Medical Home, Secretary of.

O.—Oldham Infirmary, Secretary of; Dr. I. Owen, Lond.; Messrs. P. de Otarduy and Co., Lond.

P.—Mr. H. A. Pearson, Handsworth; Mr. G. Pernet, Lond.; Mr. T. F. Poche, Dinas Powis; Plumbers' Company, Lond.

R.—Mr. A. W. Mayo Robson, Leeds; Mr. W. E. Ryves, Sheffield; Dr. C. Reinhardt, Southstoke; Dr. J. H. Robinson, Oldham; Mr. A. R. J. Ross, Lond.

S.—Earl Spencer, Althorp; Mr. W. B. Saunders, Philadelphia; Mr. Rowland Smeeth, Belfast; Dr. Shiels, Birmingham; J. T. Segrue, Ltd., Lond.; Student, Lond.; South Devon and East Cornwall Hospital, Plymouth, House Steward of; Captain Stone, Cheltenham; Dr. Spencer, St. Briavels; Scottish Equitable Life Assurance Co., Newcastle-on-Tyne, Secretary of; Swansea Hospital, Secretary of; South Hornsey Urban District Council, Clerk of; Smith's Advertising Offices, Lond.; Messrs. Street and Co., Lond.; Messrs. Street Bros., Lond.; Messrs. Sykes, Josephine and Co., Lond.; St. Andrew's Hospital, Northampton, Secretary of; Mr. S. Spokes, Lond.; Messrs. Smith, Elder, and Co., Lond.; Mr. A. Stenhouse, Glasgow.

T.—Dr. C. B. Taylor, Nottingham; Dr. R. S. Thomson, Glasgow; Mr. R. F. Thomas, Cwmaman; Thanet (Isle of), Clerk of; Taunton and Somerset Hospital, Accountant of; Dr. A. G. A. Thomson, Devizes; T. M.; Dr. F. Taylor, Lond.; Mr. G. R. Turner, Lond.

U.—Dr. J. F. Usher, Ballarat; University of Durham College of Medicine, Newcastle-on-Tyne, Secretary of.

V.—Mr. W. Van Praagh, Lond.; Mr. G. Van Abbott, Lond.; Victoria Carriage Works, Lond.

W.—Dr. J. R. Wallace, Calcutta; Dr. L. A. Weatherly, Bath; Wilts County Asylum, Devizes, Superintendent of; Messrs. J. Wright and Co., Bristol; Messrs. Wright, Dain, Peyton, and Co., Birmingham; Worthing Corporation, Town Clerk of; Mr. C. F. Wardley, Penzance; Mr. R. T. Williamson, Manchester; Messrs. Widenmann, Broicher, and Co., Lond.; Dr. H. Walsham, Lond.; Professor Windle, Birmingham; Mr. A. Waddell, Broughty Ferry; Dr. A. Warden, Paris.

Z.—Z., Eastbourne.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. R. R. Anderson, Fern Hill; A. B. J.; A. K.; A. A. B.; A. F.

B.—Dr. J. M. Barbour, Lond.; Dr. W. H. Burke, Rajput, India; Messrs. Benger and Co., Manchester; Barrett, Liverpool; Mr. H. Butterfield, Northampton; Messrs. Battle and Co., Paris; Mr. W. H. Blaber, Hove; *Bolton Chronicle*; B., Bradford; B., Lond.; Messrs. Brown, Gould, and Co., Lond.; Mr. J. N. Bredin, Potton; Dr. J. S. Bolton, Birmingham.

C.—Dr. J. Clegg, Urmston; Mr. R. H. Cowan, Wigan; Mr. E. M. Corner, Lond.; C. S. V.; Carnarvon Infirmary, Bangor, Secretary of; Messrs. E. Cook and Co., Lond.; C. R. G.; C. G. H.; C. S. J.; Mr. E. Chilcott, Woolston; C. J.; C. L.; C. B. M.; Messrs. Condy & Mitchell, Lond.

D.—Mr. R. Duncan, Banff; Dover Hospital, Secretary of; Mr. J. H. Dewan, Carrick-on-Suir; Doctor, Bedlington; Mr. H. Downes, Upton-on-Severn; Dr. J. Davis, Lond.; D. C.; Dr. H. E. Daniell, Bournemouth; Messrs. Douglas and Mason, Edinburgh.

E.—Dr. J. W. Edgar, Settle; E. F.; E. McC.

F.—F. F. M.

G.—Mr. J. B. Gabe, Morriston; Mr. J. Greet, Lond.; Mr. A. G. Garrett, Leamington; G., Bayswater; Dr. J. W. Geddes, Winterton; Mr. W. Gosse, Sittingbourne; G. W.; G. H. W. H.; Dr. Guy, Exmouth.

H.—Dr. J. Holmes, Whitefield; Mrs. Hitch, Hollington; H. C.; H. R.; Mr. C. H. Harding, Whittlesea; Miss Herrick, Ilkley.

J.—Joint Counties Asylum, Carmarthen, Secretary of; J. H. G.; J. F. H.; J. R. L.; J. H.; J. A.; J. C. P.; J. A. C. B.; J. J. K.; J. J. R.

K.—Mr. J. P. Kelly, Hoo; Mr. V. K. Kirlosker, Jamkandi, India; Dr. J. P. Kitson, Cleobury Mortimer.

The Huxley Lecture

ON

RECENT ADVANCES IN SCIENCE AND THEIR BEARING ON MEDICINE AND SURGERY.

Delivered at St. Martin's Town Hall at the Opening of the Winter Session of Charing-cross Hospital Medical School, Oct. 3rd, 1898,

BY PROFESSOR RUDOLF VIRCHOW,

DIRECTOR OF THE BERLIN PATHOLOGICAL INSTITUTE.

THE second Huxley Lecture, which constituted the inaugural address on the occasion of the opening of the Winter Session at Charing-cross Hospital, was delivered, in English, on Monday, Oct. 3rd, by Professor Rudolf Virchow, of Berlin, at St. Martin's Town Hall, Lord Lister occupying the chair. The hall was completely filled in every part and Professor Virchow was accorded an enthusiastic reception on his entrance and again when he commenced his oration. Lord Lister, in opening the proceedings, said the reception which they had given showed how grateful they all were to Professor Virchow for making the journey all the way from Berlin for the purpose of giving this Huxley Lecture. Professor Virchow required no introduction to an audience like that, and he was sure he would best consult the wishes of all if without further preface he asked him to address them.

Professor VIRCHOW said: Lord Lister, my Lords, and Gentlemen,—The honour of being invited to deliver the second Huxley Lecture has deeply moved me. How beautiful those days of remembrance will be, which the English people keep in a manner which has become a national custom, and through which the memory of their intellectual heroes is kept alive to posterity! How more touching could this act of gratitude be than by this celebration at the same place where the genius of the great man was developed? We are filled not alone with admiration towards the hero, but at the same time with grateful recognition of the institution which planted the seed of high achievement for the benefit of the student. That you, gentlemen, should have entrusted to a stranger the task of giving these feelings expression seemed to me an act of such kindly sentiment, implying such perfect confidence that I at first hesitated to accept it. How am I to find in a strange tongue words which shall perfectly express my feelings? How shall I, in the presence of a circle of men who are personally unknown to me, but of whom many knew him who has passed away and had seen him at work, always find the expression which I wish as well as a member of that circle itself could do? I do not believe I shall succeed in this, but in spite of that I repress my scruples, and it is because I know how indulgently my English colleagues will judge my often incomplete statements and how fully they are inclined to pardon any deficiency in diction if they are convinced of the good intentions of the lecturer. I may assume that such a task would not have been allotted to me had not those who imposed it known how deeply the feeling of admiration for Huxley is rooted within me, had they not seen how fully I recognised the achievements of the dead master from the time of his first publications, and how greatly I prized the personal friendship which he extended towards me. In truth, the lessons which I received from him in his laboratory —a very modest one according to present conditions—and the introduction to his work which I owe to him form one of the pleasantest and most lasting recollections of my visits to South Kensington. The most competent witness of Huxley's early period of development—Professor Foster—presented in the first of these lectures a picture of the rapidly increasing extension of biological knowledge which must have excited not only our admiration but particularly the emulation of all who study medicine. Upon me is incumbent the duty of incorporating with this presentment the newer strides of knowledge and of stating their influence upon the art of healing. So great a task is this that it would be presumptuous even to dare to attempt in a single lecture to accomplish it. I have decided, therefore, that I must confine myself to merely sketching the influence of biological discoveries upon medicine and in this way presenting an example of Huxley's work which will be most intelligible to us. I must here make a confession. When I tried to ascertain how much time would be required to deliver my lecture as I had prepared it I found, to my regret, that its delivery would occupy nearly double the time assigned to me. I had therefore to reduce it to about one-half of its original dimensions. This could only be done by means of very heroic cuts, seriously damaging in more than one place my chain of ideas.

Huxley himself was trained in the practical school of Charing-cross Hospital, but he won his special title to fame in the domain of biology. As a matter of fact, at that time even the name of biology had not come into general use. It was only recently, as I showed in my lecture on the position of pathology amongst biological studies, that the idea of life itself obtained its full significance. Even in the late middle ages it had not sufficient strength to struggle through the veil of dogmatism into the light. I am glad to be able to-day for the second time to credit the English nation with the honour of having made the first attempts to define the nature and character of life. It was, as I have pointed out in the Croonian Lectures, Francis Glisson who, following expressly in the footsteps of Paracelsus, investigated the *principium energeticum*. If he could not elucidate the nature of life he at least recognised its main characteristic. He was the first to describe as "irritability" the property on which the energy of living matter depends. He thus succeeded in setting aside the mystical idea of the spiritualistic "Archæus" which Paracelsus and his followers had placed in the forefront of their deliberations in venturing to locate the *principium energeticum*. in matter itself. How great was the step from Paracelsus to Glisson, and I may add from Glisson to Hunter. According to Paracelsus life was the work of a special *spiritus*, which set material substance in action. To Glisson matter itself was the *principium energeticum*. Unfortunately he did not confine this dictum to living substances only, but applied it to substance in general—to all matter. It was Hunter who first announced the specific nature of living matter as contrasted with non-living, but he also did not attain perfect clearness of vision because in the development of English medicine the idea has been allowed to take root and grow that life was not bound up with structure. So that John Hunter, also, was led to place a *materia vitæ diffusa* at the head of his physiological and pathological views. Hence he arrived at the assumption of so-called plastic substance, and so it happened that in place of the old Greek humoral pathology there arose a new humoral pathology—hæmatology. According to the teaching of Hewson and Hunter the blood supplied the plastic materials of physiology as well as the plastic exudates of pathology. Such was the basis of the new biological method—if one can apply such an expression to the incomplete doctrine of 1842, when Huxley was beginning his medical studies at Charing-cross Hospital. Of pathology in England John Hunter was the accepted master and so remained for many years thereafter. So great was his influence that Continental medicine also recognised it. To this I can myself testify as I was at this time at the end of my university studies. It would lead too far afield were I to recount in this place how it happened that I myself, like Huxley, was early weaned from the pernicious doctrine of humoral pathology. It must suffice to say that salvation lay in the same science which had already once before—in the sixteenth century—brought about deliverance from humoral pathology. It thus came about that Vesalius threw over authority and founded human anatomy upon direct investigation. Since then anatomical studies have been much improved. When Huxley himself left Charing-cross Hospital in 1846 he had enjoyed a rich measure of instruction in anatomy and physiology. How great this was can be gathered from the interesting statistics which Professor Foster has collected with the aid of Huxley's distinguished fellow-student, Sir Joseph Fayrer. Of the lectures which junior students attended in the three years much time was devoted to anatomy and physiology. Thus trained, Huxley took the post of naval surgeon, and by the time that he returned four years later he had become a perfect zoologist and a keen-sighted

Digitized by Google

ethnologist. How this was possible anyone will readily understand who knows from his own experience how great is the value of personal observation. For the development of independent and judicial observation is of the highest importance to young men who desire to collect rich treasure of positive knowledge. Good judgment and a long sea voyage afforded a valuable opportunity for original work and deep reflection. Freed from the formalism of the schools, thrown upon his own intellect, compelled to test each single object as regards properties and history, he soon forgets the dogmas of the prevailing system and becomes first a sceptic and then an investigator. This did not fail to affect Huxley, the Huxley whom we commemorate to-day, and in alliance with whom we can point to Hunter and Darwin. The path on which these men have achieved their triumph is that which biology in general has trodden with ever-widening strides since the end of the last century: it is the path of genetic investigation. We Germans point with pride to our countryman who opened up this road with a full conviction of its importance and who directed towards it the eyes of the world, the poet-prince Goethe. He did for plants what was done in the case of animals by Wolf, Meckel, and other members of the German embryological school. These men began with the study of the "ovulum," but this very soon showed that the egg itself was organised and that from it arose the whole series of organic developments. When Huxley after his return came to publish his observations he found the history of the progressive transformation of the contents of the egg already verified, for it was by now known that the egg was a cell, that from it fresh cells and then organs arose. The second of his three famous papers—that on the relationship between man and the animals next beneath him—limned in exemplary fashion the parallelism in all animal beings. But beyond this, stepping boldly across the border-line which tradition and dogma had drawn between man and beast, Huxley had no hesitation in filling the gap which Darwin had left in his argument and explaining that "in respect of substance and structure man and the lower animals are one." Whatever opinion one may hold as to the origin of mankind the conviction as to the fundamental correspondence of the human organisation with that of animals is at present universally accepted.

All biological science, especially physiology and pathology, and in particular all that has to be based upon experimental research, must first be investigated in animals. That which requires morphological confirmation finds support in comparative anatomy, histology, and embryology. The basis of our comprehension of the theory of medicine actually rests nowadays on minute microscopic investigation, for the elaboration of which the animal tissues form the indispensable control-object. Suffice it to say that in scientific biology the division between man and beast becomes less and less defined. But only let it be remarked that the division between the abstract man and the abstract animal is the same relation as, in a different form, obtains between plants and animals. How many definitions of this have been put forth in the course of time! If we place a given animal and a given plant side by side difficulties vanish which we had only raised by our own definition.

The greatest difficulty in the advance of biology has arisen in this way: mankind, following the natural tendency, has set the search after the unity of life in the forefront of its consideration. As a matter of fact, what is more natural than the conclusion that life as a special phenomenon must also have a special basis, and that the material process of life must be derived from a common cause? During last century an assumption was made, with ever-increasing conviction, of a special force—vital force. Nowadays we can still perceive the logical errors which this assumption rendered possible. Time has, however, passed judgment upon it and to-day no one continues to speak of vital force. And yet the necessity for a single basis of all vital manifestations remains. How is this to be satisfied? This is a question which is not alone of great theoretical interest, but which has become the indispensable foundation for practical work, and especially for medical practice. In order to reach this it is first of all necessary to dispense with all the dogmas of the schools and to seek to construct an objective picture of the nature of vital processes. As regards material construction, men and the higher animals and plants are not simple beings—on the contrary, they are put together from many units. The specific activity is present in the organism not alone in its perfect and fully grown form but also during its development and growth. How can a single power, whether we call it in the spiritualistic sense spirit, soul, or in the physical sense "vital force" or electricity, build up the organisms? Or if this power resided in a single organ, whether it is brain, spinal cord, or heart, how could those brainless, heartless creatures be explained which at the beginning of this century were the battle-ground of the mystics? There is here, in my opinion, only one theory possible. The life possessed by the higher organisms is not a single one; their life and all their activities only become intelligible when we go back to an exact representation based upon a kind of instinctive observation of the life of their parts. Each constituent part of a living organism has its special life. No one of the older authors proclaims it more distinctly than Paracelsus, but he destroyed this good idea by attributing to each living part a particular *spiritus*. The best of the succeeding biologists were held by this notion as in a snare instead of busying themselves in the explanation of this action. Those in medicine have completely turned their attention, like true observers, to the study of individual parts. As I pointed out at the Medical Congress at Rome it stands most clearly revealed in the history of pathology that the division of a body into its larger regions, then into organs and tissues, and then cells and cell territories, was the step which helped to the comprehension of disease. The study of regions was followed by that of organs and this again by that of tissues, and finally by that of the cell itself. But what is true in pathology must hold also for physiology, and, as a matter of fact, physiology has passed through the same development and phases. One gradually comes to understand that the life of intermediate parts is perfectly clear if one looks away from the *Archæi* of the organs and tissues and keeps in view only the life and the activities of the single cells. For the life of an organ is nought else than the sum of the lives of the single cells which are gathered together into it; and the life of the whole organism is not an individual, but a collective function. If such a collective being is analysed, no matter if it be a whole organism or a single organ, or only one tissue which is presented, the first requisite for it is that one should regard the single parts and cells as the factors of existence. Unicellular plants and animals have during this century been continually more fully and better studied; botanists and zoologists have become the teachers of the biologist and the pathologist. The discovery of the development of complete beings from the ova of animals and the corresponding germ cells of plants has bridged the gap between isolated living cells and higher organisms. In a medical school, where the teaching is almost entirely concerned with human beings, we might put this sentence very prominently, "The organism is not an individual but a social mechanism." An exact analysis of this mechanism always brings us at last to cells; they are the ultimate constituents of all tissues. Hence we call them living elements and regard them as the anatomical basis of all biological analysis, whether it has a physiological or pathological object in view. Now, two particular propositions must be stated: (1) that living organisms, like every organ and tissue, contain cells; and (2) that the cells are composed of organic chemical substances which are not themselves alive, but the mechanical arrangement of which determines the direction and power of their activity. The old students with their theory of the so-called plastic exudates in their earliest studies translated into our latter-day paths would recognise this continuity in most pathological new formations. It would establish the grounds for the dogma of the origin of life from non-living matter. Experience has taught us the exact opposite.

I may here speak a little more personally than is elsewhere my intention. Perhaps it will be more intelligible to the students of this hospital and will make more impression if I relate how I myself arrived at my views. It was towards the end of my academical studies, more than fifty years ago, that I had to take up the work of assistant in the ophthalmic clinic of the Charité Hospital at Berlin. We had severe cases of keratitis, but I saw in them no exudation. Numerous cataract operations were performed; the wounds were closed, but not by plastic exudation; this was absent from all corneal scars. Could this be explained by the circumstance that the cornea, apart from its circumference, is a non-vascular tissue? I then turned my attention to the non-vascular tissues; first to the articular cartilage, and behold, here also I found the greatest changes without the presence of exudation, or at any rate of plastic exudation. My experimental studies then extended

Digitized by Google

to the walls of the larger arteries and then also in part to the veins, and they showed equally that they can undergo great changes without even a trace of exudation. Later investigations on endocarditis led to the same result, provided that paricta1 thrombi are not regarded as exudation. In all these cases and in every place we found changes in the tissue cells—active, such as multiplication of nuclei, or passive, such as fatty degeneration. It is not necessary to go further into the matter to show how great is the action of these pseudo-exudative processes. Most of these processes are of the nature of proliferations. Whoever calls a proliferative layer an exudation will never obtain an objective view of the proceeding. There is not the slightest necessity for the genuine observer to hold to the arbitrary and totally erroneous formula of a plastic exudation; there is no such thing as plastic exudation which is ever simply amorphous, the cells which have been found in it have not arisen there. It is proved in numberless places. The doctrine of the discontinuous origin of pathological new formations is set aside. Every such new formation presupposes tissue from which its cells arise, that is, its matrix. Pathology has been late in arriving at a knowledge of this correspondence, but I think it has acquired special value for biology in general. Proliferation is an active property of special cells but it cannot be performed by all cells alike. That in no way alters the fact that it can only be performed by cells. It is just as little a function of the entire organism, for this would then have to be unicellular. In this property lies the explanation of origin from a single egg, the wonderful process which comes to pass but once in the life of the animal. Once the tissues have arisen each cell of the tissue may, in respect of proliferation, be compared to an ovum; it brings forth a new progeny from which new tissue grows, this tissue bearing, as a rule, the stamp of its matrix; it is built on the maternal type. And here lies the key to the knowledge of heredity, that puzzling appearance with which mankind has ever busied itself.

It is the custom to describe as hereditary all diseases which reappear in different generations of the same families. Thus, one speaks of hereditary tuberculosis and hereditary cancer. It is, in fact, not difficult to produce genealogical tables which demonstrate the recurrence of paternal maladies in children and grandchildren. Much trouble has been devoted—in my opinion without result—to the seeking of the germs of such diseases in the ovum or the semen. One is compelled to pass on to generations of cells which took origin after conception. As we pass from the time of conception the more numerous do we find the alterations in the formation of cells and in the formation of embryonic tissue. At the same time there is a greater possibility of the alteration having arisen after the formation of the first cells and hence that the existing cause may have commenced to act at that time. If we set aside this possibility nothing else remains but to assume that from conception from the organs which produce the disease a predisposition is transmitted which is already present in the earliest cells, even if it cannot be recognised in them.

There is a highly remarkable question which every year claims the attention of medical men more and more, and this is what is described as *heterotopia*. It has long been known that hairs are present not only on the external skin, to which they properly belong, but also in internal organs, where they are quite out of place. Such structures are known as dermoids. As a matter of fact, in fœtal life the smaller or greater rudimentary fragments can be separated from all their natural places of abode and removed to other spots, where they, so to speak, find a new home and can undergo all the further changes which are dependent on their cutaneous nature. It is thus that cysts and tumours can arise from them. But the most remarkable examples of such are found in certain glandular organs which present the unities of similar parts. Amongst these a high place is taken by two organs which have recently demanded much attention—the thyroid and suprarenal glands. On their surface may often be observed the crushing forward and progressive isolation of separate parts in the form of nodules or small lobes. But occasionally these nodules pass completely out of association into the main body of the gland, and are found disconnected in a perfectly strange place more or less removed from their seat of origin. In the case of the suprarenals the cells travel to neighbouring spots in the interior of the kidneys and the deeper parts of the peritoneum as far as the pelvis. And at all these phases they may undergo further change as a further starting-point for tumour formations.

It is inadvisable to go into minuter details; only a few of the greater landmarks can be referred to. One of them I will mention briefly, as I have written many long papers upon it—the necessity for distinguishing between the cause and the essential nature of infectious diseases. The nature of the disease depends upon the behaviour of the organs and tissues with which the bacteria and their metabolic products meet. From my point of view this distinction is of paramount importance. First, there is the general relation of the smaller parasites to the diseases determined by them. Under one name which takes us back into the old days of humoral pathology, and which I was the first to introduce into common parlance, are grouped all the processes which are produced by the invasion of morbid substances under the general designation of infection. The relation between infection and intoxication was presumed and it was not without good reason that the designation was retained. Among the innumerable infectious diseases which affected not only man but animals this remarkable property in contagia came to the front—that they multiplied in the body and so, besides infection as such, produced an immeasurable quantity of fresh virulent substance. In this respect they approach the living beings and the idea arose that they were themselves alive. With the discovery of parasitic animals conjecture became fact and nothing was easier than to generalise this fact and assume the presence of independent organisms in each contagious disease. It became known that parasitic animals and protozoa can so give rise to infection. Between bacteria and fungi there is more than a slight difference, but for convenience the name of bacteria is retained as a general designation. Owing to the novelty of the circumstances in which they are placed botanists have not even yet succeeded in their customary duty of giving every new plant its special name. This omission is understood and forgiven, but it does not in any way alter the erroneousness of the theory which attributes every impurity to bacteria on the sole ground of its contagiousness. It may be said that the contagious nature of disease shows suspicions of bacterial origin, but it should not be simply called that, though it allows the conscience to sleep. Some of the most important contagious diseases have succeeded in resisting the struggle to find in them a parasitic contagion. For example, many have been the sanguine hopes of finding the parasite of syphilis and as many have been the failures; the coccus of gonorrhœa alone has been discovered, the bacterium of syphilis remains a desideratum. You will remember the certainty with which it was expected that a parasite was the causal agent of variola. More than one was found, but none pathogenic. In hydrophobia all appearance seemed to promise that it would prove to be a micro-parasitic disease. Its contagion is undoubted; the vaccine has been prepared and yet no one has been able to cultivate a specific bacillus. The same may be said of some other specific diseases. Painful as it may be one can do nothing but observe. Perhaps the pathogenic bacteria will be found, but as long as they are not discovered all assumption is useless if not dangerous. To have learned this is to have made a mighty stride in the biology of disease.

A further question is the mode of infection. As long as infection by animal parasites was regarded as the type of infection generally the destructive action was described as the result of a mechanical action just comparable to a bite or devouring. The exact study of the larger entozoa soon brought about a complete conversion.

The feeding of bacteria and vegetable and plant-like parasites has to be regarded in the same way. They certainly injure the tissues in which they reside by the consumption of materials, but their action is not limited to this. This much has been already learned in the study of fermentation and putrefaction. It is admitted that organic matter is destroyed by them, but in addition they produce new substances, some of them eminently poisonous. It has been known for centuries that alcohol is produced by fermentation, but the putrefactive poisons could not for a long time be isolated. To the whole group the new term of toxins has been applied. They are in part crystallisable, invariably diffusible substances, which are bound up neither in cells nor other formed elements, though they are produced by the cell action of the parasites. They are now described as metabolic products, a term which has far more

Digitized by Google

sound than sense. In former times people were content to call them secretory products, and I think it would be better to stand by this term.

It would be called carrying coals to Newcastle were I to sketch in London the beneficial effects which the application of methods of cleanliness has exercised upon surgical practice. In this city, where the man still lives and works who by devising this treatment has introduced the greatest and most beneficent reform that the practical branches of medical science have ever known, everyone is aware that Lord Lister has had results which the new theory of fermentative and septic processes fully confirms. Before anyone had succeeded in demonstrating by exact methods the microbes which are active in various diseases, or in establishing the special functions which they performed, Lord Lister had learned in a truly prophetic revelation the means by which protection against the action of putrefactive organisms can be obtained. The opening up of further regions of clinical medicine to the knife of the surgeon and a perfect revolution in the basis of therapeutics have been the consequence of the work of Lord Lister, whom I am proud to be able to greet as an old friend to-day. Already and always he will be reckoned amongst the greatest benefactors of the human race. May he be long spared to remain at the head of the movement which he called into existence.

It remains for me to say a little word concerning the other great problem, the solution of which the whole world is awaiting which anxious impatience. I refer to the problem of immunity in the sense of practical artificial immunisation. It has already happened once that an Englishman has succeeded in applying this to the nearly complete destruction of at least one of the most deadly infectious diseases. Jenner's noble discovery has stood its trial as successfully as he hoped. In our hands vaccination is, with the aid of the Governments, spreading continually. In the same way the work of Pasteur also raises our admiration and the new doctrine of antitoxins is continually acquiring new adherents, but it has not yet emerged from the conflict of opinion. Still less is the secret of immunity itself revealed. We must still become well accustomed to the thought that only the next century can bring perfect light and certainty on those points. The homœopathic notion that toxin and antitoxin are one and the same seems so foreign to our biological ideas that very many experimental and practical proofs will be required before it can be admitted into the creed of the future. We must succeed before then in finding the means of strengthening the cells in their fight against bacteria.

We must, in conclusion, turn once more to the special cells which build up the body and which arise from proliferation within the body. These have numerous analogies with microbes. They also are independent living beings, or, as they say, elemental organisms implanted in the social structure of the body. They can be removed and transplanted into new situations. The process is always bound up with a certain number of living elements. It is always cellular in character. It is not the flowing blood which makes the tumour or cells; it is the mother cells from which all new formation arises. From this consideration I have drawn this conclusion on the local action of the cells bound up in certain parts. Cellular pathology admits the principle of destroying local disease by local measures, be those measures medical or surgical. It is with great joy I see this becoming more generalised. Hence follows in surgery the recommendation of early operation for the destruction of the focus of disease. Those cells also, just as do bacteria, exercise chemical influences apart from the destruction which they effect by absorption. They secrete chemical substances and these appear first as tissue fluids, passing later into the circulation. Thus arises a change in the composition of the flowing juices, particularly of the blood—in fact, a dyscrasia. This is, as I have always explained, a secondary dyscrasia, quite distinct from the primary dyscrasias of the humoral pathologists, by localization of which topical diseases, and especially tumours, were supposed to arise. According to my view, each dyscrasia is determined by the taking in of products of tissue secretion which may now be called metabolic products or recrementitious substances. The tissue juice and excreted material has obtained of late years much attention and has provided materia medica with thyroid juice and thyroidin. New substances resembling alkaloids or albuminoids are isolated from various organs, experimentally tested, and technically worked up. So arose injection therapeutics, on the results of which we are not yet in a position to pass a final judgment. But everyone who is sufficiently unprejudiced must admit that they have in many cases been good. Experience will determine the value of these methods. You must learn by the aid of practice to deduce lasting theoretical proofs. But never forget that the source of all these substances and secretions is the cell activity of living tissue, and that its therapeutical or pathological remedial action on the organs or tissues can accomplish no result besides that of exercising a regulating influence on cell activity. May the Medical School of Charing-cross Hospital continue upon the newly opened paths and do so fortunately, and at the same time may its students never forget that neither the physician nor the naturalist dares to dispense with the cool head and calm spirit of practical observation and critical judgment.

Dr. T. H. GREEN (physician to the hospital), in the unavoidable absence of Sir Joseph Fayrer, proposed a vote of thanks to Professor Virchow. He thought it would be very difficult to adequately represent the measure of their indebtedness to the lecturer for coming over from Berlin, whereby he conferred a great honour not only on their medical school but also on the whole medical profession of this country. He believed that never in this city had the session of a medical school been opened under such favourable auspices as theirs was that day. Thirty years ago he had the good fortune to be a pupil of Professor Virchow in Berlin and it was therefore a source of great gratification to him to be allowed to propose that vote.

Dr. BLACK seconded the motion, remarking that he also could look back with pride at having been a pupil of the distinguished lecturer.

The motion was put from the chair and carried by acclamation, Lord LISTER expressing his sense of the profound debt they owed to Professor Virchow for his learned, profound, and beautiful address.

Professor VIRCHOW, in reply, said: Gentlemen, allow me to express only somewhat of the thanks I feel for this glorious reception. It was one of my warmest wishes to see Charing-cross Hospital, as the scientific birthplace of such great men as Livingstone and Huxley and others who followed, and I promise you that I will never forget this reception and the days when I was in your midst. And may you, also, my young colleagues and students of this hospital, see in these great examples of whom I have spoken this evening prototypes of a good, honest, scientific life.

An Introductory Address

ON

THE IMPORTANCE OF PERSONAL CHARACTER IN THE PROFESSION OF MEDICINE.

Delivered at the Opening of the Winter Session of the Medical Department of the Yorkshire College, Leeds, on Oct. 3rd, 1898,

BY CHARLES J. CULLINGWORTH, M.D. DURH., F.R.C.P. LOND.,

OBSTETRIC PHYSICIAN TO ST. THOMAS'S HOSPITAL, LONDON.

MR. DEAN AND GENTLEMEN,—I consider it a very great honour to have been invited to take so prominent a part in the interesting ceremony of to-day. As an old Leeds student and a native of this city it is with both pride and pleasure that I observe the unmistakeable signs of healthy prosperity in my old school, now the Medical Department of the Yorkshire College. Your buildings, your laboratories, your teaching appliances, and, of course, your fine hospital, will not only bear comparison with other similar institutions in this country but are so modern and so complete as to warrant a passing twinge of envy in the breast of a London teacher. I should, however, be making but ill use of an exceptional opportunity if I wasted the few minutes at my disposal in elaborate compliments, however well deserved they may be. My desire to-day is to say a few words which

Digitized by Google

shall if possible be encouraging and helpful—first to those of my younger brethren who are still *in statu pupillari*, and, secondly, to those who have just completed their curriculum and are about to engage in that struggle for existence which is apparently becoming every year more severe and more hazardous to the well-being of the individual practitioner both "in mind, body, and estate."

First, then, allow me to address myself to those who are still students. It is now a good many years since Sir James Paget published in the St. Bartholomew's Hospital Reports a short paper embodying the results of an inquiry as to what became of a thousand of his pupils within fifteen years of their entrance at St. Bartholomew's Hospital. It was a most interesting article and is still well worth reading in its entirety, for what was true of the medical student of thirty years ago is, in the main, equally true of the medical student of to-day, and, so far as I am aware, no similar inquiry has been made either before or since. Of the total number of Sir James Paget's pupils during the period embraced in the inquiry (1839–59) many had, of course, been lost sight of, but the career of 1000 of them was known either to Sir James Paget himself or to his colleagues, the late Mr. Callender and Mr. (now Sir) Thomas Smith, both of whom were engaged with him in the investigation. Of the 1000, 23 had achieved distinguished success; 66 had achieved considerable success; 507 had achieved fair success; 124 had achieved very limited success; 56 had failed entirely; 96 had left the profession; 87 had died within twelve years of commencing practice (21 of them from diseases incurred in the exercise of their professional duties); and 41 died during their pupilage (17 of them from phthisis). It may be explained that in this summary "distinguished success" means that those classed under this heading had gained leading practices in counties or very large towns, or held important public offices, or had become medical officers of large hospitals or teachers in great schools. Those are stated to have attained "considerable success" who had gained, and still held at the time the paper was written, "high positions in the public services or leading practices in good districts," or who had already retired on their earnings, or who had won for themselves "much more than ordinary esteem and influence in society." The rest of those who could be said to have achieved any sort of real success constituted the third class. This class, which might be called the moderates, embraced more than half the total number of those whose histories were known. Of the other classes I need not here speak in detail beyond calling attention to the curiously large number that left the profession, nearly 10 per cent. of the whole. Most of those who are classed under this heading discarded the medical profession for other pursuits—the Church, the army, the stage, commerce, and agriculture. It was the concluding portion of the paper, however, which made at the time the strongest impression on my mind and which has induced me, even after this lapse of years, to bring it before you to-day. "Of course," says Sir James Paget, "in watching and reflecting on the careers of my pupils I have come to some strong beliefs on subjects of medical education, but this is not the place for publishing them. Only one I will set down, which may be of use to future pupils and is justified by some hundreds of personal recollections. In remembering those with whom I was year after year associated and whom it was my duty to study, nothing appears more certain than that the personal character, the very nature, the will of each student had far greater force in determining his career than any helps or hindrances whatever. All my recollections," he continues, "would lead me to say that every student may draw from his daily life a very likely forecast of his life in practice, for it will depend on himself a hundredfold more than on circumstances. The time and the place, the work to be done, and its responsibilities will change; but the man will be the same except in so far as he may change himself."

It may be said that this was all very well thirty years ago, but that times have changed and that whereas it may have been and, no doubt, was then possible for a man with character and perseverance by sheer force of good behaviour and steady plodding to come eventually to the front, no man could do so to-day unless he also possessed a more than average share of intelligence. For the general standard of knowledge in our profession has been raised and the range of knowledge greatly widened, so that much more is required to-day both in quantity and quality even of the ordinary pass man, to say nothing of the honours men and prize-winners. This way of putting the matter sounds exceedingly plausible, but it leaves out of view the fact that entrance into the profession is now guarded in a way in which it was not guarded during the period of which Sir James Paget was writing and that whereas a man could then enter upon his course of medical study without having given any proof of having received a fairly liberal education it is impossible for him to do so now. The preliminary examination in general education which must be passed before a student can register, though not a very severe test, is quite severe enough to keep back the hopelessly ill-educated man whatever good qualities he may possess. Hence the struggle is not, as might be supposed, between the man who has character without intellectual training and the man who has character with it, but between the man who has intellectual training *with* character and the man who has intellectual training without. In such a struggle victory rests in the end with the man who, to his intellectual attainments, adds character. As Sir James Paget says, "the time and the place, the work to be done, and its responsibilities" may change, but the personal character of the student remains now as then the chief factor in determining his ultimate career.

It is sometimes said that the men who win prizes during their student life are not the best men and seldom fulfil the expectations of their teachers and friends. I have a shrewd suspicion that the author of this dictum was some ingenious but lazy man who thought to cover his own deficiencies by belittling the successes of his more industrious fellow-students. Let anyone who is interested in the subject and anxious to arrive at a correct estimate of the amount of truth in this statement take up a London University Calendar and refer to the honours lists in the various subjects of examination for the degrees in medicine. Here and there, of course, he will find an unfamiliar name amongst those who from year to year have taken the highest honours, but he will probably be astonished at the comparatively large number of names which have since become well known and, in many cases, even distinguished as those of recognised leaders of our profession. Amongst those, for instance, who in the years long gone by obtained scholarships and exhibitions in the examination for the degree of Bachelor of Medicine will be found the familiar names of Richard Quain, Edmund Parkes, George Johnson, Alfred B. Garrod, William S. Savory, Samuel Habershon, John S. Bristowe, J. Russell Reynolds, Henry Thompson, Joseph Lister, William Roberts, and William H. Broadbent, all of whom may certainly be said to have fulfilled the promise thus given of future distinction and success. I speak of the London University because I happen to know it best. I have no doubt the same is true of the other universities, including your own still youthful Victoria University, in which, as some of you know, I take a special interest as having borne a somewhat active part in the work of administration during the anxious and perilous years of its early infancy. Holding this view of academic distinctions, the spectacle of a student stepping forward to receive a prize has for me far more than a mere passing interest. I am conscious of having witnessed an important scene in the drama of a life. He must be a singularly unemotional person who can, for instance, witness such a ceremony as we have witnessed to-day without having his pulses stirred and his sympathies excited. For surely no study is so absorbing as that of the development of the story of a human life, especially when events have shown that life to be one of more than ordinary promise. I shall certainly hope and expect to hear again of the recipients of to-day's honours and to learn that the successes of to-day have been a mere forecast of the many which are to follow. The conditions of success are pretty much the same in student life as they are elsewhere. The essentials—those conditions, namely, upon which all the others necessarily rest—have long ago been summarised in the well-known motto, "Mens sana in corpore sano." There is at present no need to emphasise the latter part of this motto. The tendency appears to me rather in the direction of giving it undue prominence. I do not yield to any in my sense of the importance both to the race and to the individual of out-door games, athletic exercises, sports, and all the various means of developing the capacities of the body, and keeping them at their best. But when I find them the all-absorbing topic of conversation, when I realise that athletic achievements are the surest way to distinction and popularity, when I observe that an increasingly large part of

Digitized by Google

our newspapers is filled with the record of them and that no part of the day's news is read so widely or so eagerly, and when I am actually assured that schools and colleges are selected on considerations affecting their athletic fame rather than their reputation for scholarship, I am tempted to wonder whether the first part of the motto I have quoted is receiving sufficient attention and whether the needs of the body are not absorbing a little more than their share.[1] "Propose this test—," says Browning,

> "Thy body at its best,
> How far can that project thy soul on its lone way?"

I have said enough, however, on this head. The strong common sense of our English-speaking race may be depended upon for sooner or later adjusting the balance and for taking care that whilst the body receives its due share of cultivation the needs of the mind shall not be seriously overlooked.

"There is no profession," said an English bishop, preaching recently to a medical congregation in St. Paul's Cathedral, "except perhaps that of the Church, in which character counts for so much as it does in the profession of medicine." If that be true, and I feel certain that it *is* true, it becomes of the highest importance to keep up during student life a high moral standard. The true greatness of any school or college, medical or otherwise, must always depend in the long run not upon its athletic or academic achievements, but upon the high standard of its moral tone. If you desire your own college to enjoy the best kind of pre-eminence, it must be by every one of you, senior and junior, helping to keep up the standard. You who are here to-day for the first time will find it a great change from ordinary school or college life, with its discipline and supervision, to the life of a medical student. During a great part of every day you will be free to go where you like and do what you like, and your future much depends upon the use you make of this freedom. And you who are seniors must remember that the juniors will take their tone from you. The influence of the senior students upon the junior is incomparably greater than that of the teachers on either and gives the senior student a position of great responsibility.

I must now, however, pass on to say a word to those of you who will no longer be students in the technical sense of the word—those, I mean, who have completed their curriculum and obtained their diplomas to practise. Students in the broader and equally true sense of the word you will, I hope and believe, continue to be to the end of your lives. In fact, your experience will be very different from that of the majority of your brethren if, after being a few years in practice, you do not find that you have learnt more of your profession since you became qualified than you did before. At present, no doubt, the feeling uppermost in your minds is one of thankfulness that you have at last come to the end of what at one time must have appeared to be an almost interminable series of examinations. I entirely sympathise with my old friend and teacher, Mr. Pridgin Teale, in his opinion that the medical student is over-examined. And yet it is difficult to see in what other way than by examination his knowledge and his fitness to practise his profession can be adequateiy tested. I am quite sure of this, however, that although Mr. Teale did not succeed in carrying his resolution in the General Medical Council, his forcible speech in moving his proposition and the discussion which followed will prove to have had an excellent effect upon the examiners. It is well that examiners should be reminded from time to time of the main object of examination—namely, to test the fitness of the candidate to be entrusted with the care of the sick. The importance of keeping this in view was brought home very forcibly to all who were present by an amusing incident which took place at a meeting of the board of studies when the regulations of the Victoria University were under discussion. A member of the board, overflowing with compassion for the unfortunate candidate, proposed to lower the pass standard for the M.B. degree from one half of the maximum number of marks obtainable to one-third. It was a bold suggestion, and after the resolution had been duly seconded, there was for a few moments an ominous silence. Then one of the arts professors rose and asked the chairman, in the most innocent manner, if he was correct in supposing that this degree would confer upon its possessor a legal qualification to practise his profession. The chairman replied that it would. "Then I presume," continued the professor, still in the blandest tone, "that if we vote in favour of this resolution it will be equivalent to saying that we shall be quite satisfied if, when the newly qualified graduate has become the medical attendant in our own families, he is correct in his diagnosis and treatment once out of three times." It is needless to say that nothing more was heard of the resolution. Obviously the community must be considered in this matter as well as the candidate. But I am now addressing those more especially to whom the question of examinations has fortunately ceased to be of immediate personal concern and I may therefore leave a subject which is always liable to awaken at least *some* unpleasant recollections.

It is well for those of you who are about to enter upon the practice of your profession to be reminded at the outset that the practice of the medical profession is not altogether a life of luxury and ease. You will have a great many unpleasant experiences. You will find, for example, that you will not have one hour out of the twenty-four which you can positively call your own—in the sense, that is, of being free from the liability to interruption by a professional call. You will sometimes feel, when you have an anxious case under your care, overwhelmed by a sense of awful responsibility. You will then realise what it is to have in *your* hands, resting on *your* decision, the issues of life and death. Nothing can make these things endurable but enthusiasm. You must love your profession with a devotion not merely sufficient to counterbalance all its difficulties and drawbacks, but intense enough to make you blind to them. Given this devotion and the vocation of the medical man becomes, to my mind, the finest in the world.

I spoke a few moments ago of the danger of men during their student life, in their eagerness to promote the health of the body neglecting the cultivation of the mind. This danger is by no means at an end when a man has left the school and hospital and has entered upon active practice. Henceforward it takes the form of a tendency to become absorbed in his profession and to neglect other means of mental cultivation. None of us is strong enough to bear with impunity the strain of professional life without some kind of habitual mental recreation. It is therefore of the highest importance to set up a hobby. It does not much matter whether the hobby be a branch of natural science, or a department of general literature, or something different from either. The essential thing is to have an intellectual hobby of some kind, so as to be saved during the absorbing activities of our professional life from professional narrowness and that partial atrophy of the mental faculties which comes of disuse, and also in order to be provided when our working days are over with an unceasing source of wholesome interest.

The keenness of the struggle for existence is constantly in danger of making us forget our high calling, forget that we are members, not of a trades' guild but of a learned profession. I would not on any account utter one word in disparagement of trade. It would particularly ill-become me to do so in a city whose trade is the source of her greatness. But I hope I may, without offence, venture to point out that the commercial code of ethics differs in some important respects from the professional code. The first consideration of the business man, for example, in regard to any given transaction is how it will affect his own interests or the interests of those whom he represents. It is for his customers to judge for themselves how far *they* are likely to benefit by the bargain. The professional adviser, on the other hand, is expected to make his patients' well-being his chief care and not to be influenced in the advice he gives by motives of self-interest. Mr. Brudenell Carter tells us that the late Sir Prescott Hewett was in the habit of saying that it was not enough for a medical man to be honest—he must be chivalrous. We are ready enough to take to ourselves the title of a noble profession, but we must remember that to be truly noble our profession must set before it, and act up to, a high ethical standard. Its spirit and its methods must leave no room for the taunts of cynicism. There must be amongst its members no mean attempt to displace professional rivals by offers of cheaper service or to discredit them by whispered suggestions of professional incompetence. There must be no aping of the advertising methods of the charlatan or lowering our professional societies by the introduction of some of the more objectionable features of trades'

[1] To show that this is not an over-statement of the exaggerated and even absurd importance at present attached to these matters, let me give an instance in point. In the university cricket match a representative of Oxford made a heavy score, what in cricketing language is called "a century." I am told that this gentleman thereupon received two telegrams, each of them offering him a mastership in one of our public schools.

Digitized by Google

unionism. There must be no practising for private gain under the misleading name of a dispensary or indiscriminate recommendation of costly methods of treatment in which the prescriber has a pecuniary interest. And yet, I fear, some of these things are not altogether unknown amongst us. We want you of the coming generation to realise that the fair fame of our beloved profession in the immediate future rests with you. We trust to you to keep up its best traditions and to maintain that reputation for nobility of aim and conduct which it has hitherto possessed and which of right belongs to it.

Let me conclude with one or two extracts from a very ancient document, dating from the fifth century before the Christian era, and known as the Oath of Hippocrates. The best authorities consider it highly probable that it was written by the great sage himself. If not, it is practically certain, from internal evidence, that it was written in the Hippocratic age. It appears to be in the nature of a declaration made by the pupil when the master is about to undertake his instruction in the art of medicine. "I swear," says the youth, "by Apollo the physician, and Æsculapius, and Hygeia, and Panacea, and all the gods and goddesses, that according to my ability and judgment I will keep this oath and stipulation. I will reckon him who taught me this art of medicine as dear to me as my parents. I will share my substance with him and relieve his necessities if required. I will look upon his offspring as my brothers and if they wish to learn medicine will teach them without fee. ..... I will prescribe such a regimen for my patients as shall, according to my ability and judgment, conduce to their benefit. I will avoid whatever is evil and unjust. ..... In innocence and in purity I will pass my life and practise my art. ..... Whatever houses I enter I will enter them for the benefit of the sick, and I will abstain from every intentional act of mischief and corruption. ..... If I see or hear in the exercise of my professional practice, or even apart from it, anything in the life of men which ought not to be spoken of abroad I will not divulge it, regarding in such case discretion as a duty. While I continue to keep this oath unviolated may it be granted to me to enjoy life and the practice of the art, held in perpetual respect by all men. If I violate it and perjure myself may the contrary be my lot."

Is it possible to conceive a finer testimony to the high standard of professional conduct aimed at in those remote days? May you and I throughout our professional lives emulate the generous and pure spirit which inspired these famous words. If in the battle of life that is before you anything that I may happen to have said to-day may help you to fight manfully and to win your way to honour and success I shall indeed be glad. "I have great confidence," says our dear old friend Wendell Holmes, "in young men who believe in themselves. ..... When a resolute young fellow steps up to the great bully, the world, and takes him boldly by the beard, he is often surprised to find it come off in his hand and that it was only tied on to scare away timid adventurers." And so, with these closing words of encouragement, I bid you one and all God speed.

PRACTICE IN AUSTRO-HUNGARY.—Notice has been given by the Austrian Minister of the Interior that after the beginning of next year the right to practise medicine will be granted to Doctors of Medicine in Austria proper only or in Hungary only. Hitherto the privilege of practice has extended throughout the empire.

DURHAM UNIVERSITY COLLEGE OF SCIENCE.—An ordinary general meeting of the governors of the Durham University College of Science was held on Oct. 3rd, the Dean of Durham, warden of the University, presiding. The balance-sheet showed that the donations had amounted to £44,552, the scholarship endowments, bequests, &c., to £7419, and loans to £32,000. With other items the total receipts on account of the College amounted to £85,707. Investments amounted to £2704, the value of ground and houses bought with the College site was £13,526, and the value of the College buildings was £59,050. There was a deficiency of £9406 on revenue account. The revenue account showed the total receipts to be £16,224, the total payments amounting to £16,453. The retiring councillors—Mr. William Cochrane, Professor Philipson, and Dr. Spence Watson—were re-elected. There were two vacancies on the council by the deaths of Dr. Charles Mitchell and Mr. John Philipson. Mr. Crawford Smith and Mr. Watson-Armstrong were elected to fill these vacancies.

Opening of the Session 1898-99.

MASON COLLEGE, BIRMINGHAM.

INTRODUCTORY ADDRESS BY PROFESSOR MICHAEL FOSTER, F.R.S., PROFESSOR OF PHYSIOLOGY IN CAMBRIDGE UNIVERSITY, ON "THE NATURE AND FUNCTION OF A UNIVERSITY."

GENTLEMEN,—So soon as I began to strive to put together a few words to speak to you on this occasion there came into my mind, not once only but again and again, the thought that Birmingham is soon to have a University of its own. I have the honour this evening to give the signal for the commencement of the winter session of medical studies. For many years in the past the medical school connected with the General Hospital and the Queen's Hospital pursued an honourable career as a provincial school of medicine. Of late years that independent school has become—may I not say happily become?—the Queen's Faculty of Medicine in the Mason University College. Soon, we hope and believe, yet another step will be taken and the teaching of medicine in Birmingham will be carried on not as the action of an isolated hospital, not as part of the work of what some would call a mere college, but as the labour of the constituent Faculty of a Midland University. Hence I have been led to consider how this step will affect medical studies here, and this consideration naturally began with the question—What is the real nature of the step? What does it mean? This, again, leads in turn to the question—What is a university? How does it differ from a college or from a school, or from any other institution devoted to learning? What are its essential features? What are the central ideas running through it which distinguish it from everything else? Many would say: "A university is a machine for granting degrees."

[There were others, Professor Foster went on to say, who thought that a university was a place dealing with all knowledge. Others thought that it was a place where all benefit by what is learned and taught without any one receiving profit for any particular line of life. To answer the question of what is a university we must consider what the original universities were. They were guilds or corporations of learned men—a number of men bound into a body for some special purpose. Inquiry was their main object, and secondly came teaching—teaching their scholars to succeed in one of three walks of life, the Church, law, or medicine. The old trade guilds had two degrees—one the apprentice, the other the master. So had the guild of learning, only it adopted special names and the apprentice became the scholar while the master (*magister*) retained the same name or else rose still higher in the scale of learning, being called "Doctor." Admission to the "degree" was only granted after "repeated and prolonged interviews" of the scholar with a troop of learned masters. Professor Foster continued:—]

"The university of old was a guild by means of which the beginner was brought under the influence of the sage; a guild in which those who knew gave of their knowledge to those who wished to learn, amid surroundings which were rich in aspirations for wider and fuller truth; a guild continually made young by the continual bringing into the fold of new members, but only such as had proved upon trial their love of knowledge and their power to grasp it. Are not these things the aim and the tokens of the university of to-day?

[Professor Foster, after urging the point that too much value should not be placed upon a degree, for it could have only a relative and not an absolute value, and advising that examinations must not be strained overmuch, proceeded:—]

Let me, however, turn aside from generalities such as the above to say a few words about the particular degrees which are special to the present occasion—degrees in medicine. I

Digitized by Google

shall, I trust, carry you with me when I say that the object of the institution of medical degrees is to select out of those who press forward to join the medical profession the men who give promise of becoming real doctors. It is a means of marking those who may be expected to show by their subsequent careers that they possess the power to heal the sick. When in the early days of the universities the academic rulers prescribed certain studies for those who sought to be doctors of medicine and insisted on those studies being diligently and successfully pursued, they did so under the conviction that each and all of these studies gave power to the arm of the doctor in his struggle with disease. As I have said, they believed that what they taught was useful and necessary for practical life. The degree they bestowed was undoubtedly honourable, but they never looked upon it as ornamental. They gave the doctor a special robe that men seeing it might know at once through what studious labours the wearer had passed and how he thereby differed from other men. They never thought of it or of the degree as a thing to be flaunted, for pride's sake, in the face of the people. Let us follow their example. Let us, as they thought they did—they may have been mistaken in their details, but this does not detract from the value of their purpose—see to it, that the studies which are demanded of the doctor are those which are calculated to fit him in the best possible way for his task in life. Now, success in a medical career, and that is the real proof of the possession of power to heal or to relieve the sick, is contingent on many things, on the concurrence of many diverse qualities. Of these some, and those by no means unimportant, cannot be taught by any professor, cannot be tested beforehand in any school; of such, the world is the only schoolmaster and life itself the only examiner. One need not live long to have come across men brimful of knowledge, quick to see, sure in judgment, and nimble of hand, who yet have failed to gain power over patients, because they have lacked something. At the very best any test which a university can apply is a partial one, and is, viewed as a guarantee that the patient will find what he expects, in many ways imperfect.

[This being so, went on Professor Foster, our tests should be of such a kind as to anticipate as far as possible the judgment of the world. There was so much to be learned nowadays that some choice must be made in the things which he who sets out to be a doctor is bidden to learn. He continued:—]

An examination for a medical degree, as I have asserted, is or ought to be a test whether the examinee gives adequate promise of being able to cure or relieve the sick, whether he possesses the knowledge and ability to apply the teachings of science to the removal, mitigation, or prevention of disease. It is not to be used, as some other examinations are or may be, to test a man's mental agility and alertness, his power of rapid and correct expression, his coolness and presence of mind amid difficulties. It ought to be directed solely to appraising his professional skill; simply this, all else is irrelevant. Now I can quite conceive that this might be satisfactorily accomplished by a final clinical examination—a prolonged and searching examination it may be, but one essentially clinical, or at least professional in nature. It would, I believe, be possible to conduct such an examination in such a way that the candidate must show by his attitude towards clinical problems whether he had rightly grasped pathological truths, and this in turn in like manner would show how far he had laid hold of pathology and therefore of chemistry and physics. Our justification for insisting on the study of these preliminary sciences is that a knowledge of them leads up to, being the basis of, clinical insight and skill. If this be so the effects of those studies ought to be recognisable at the end. If our system of training be really a sound one, if at each step an indelible stamp is left on the learner, then at the end we ought to be able to trace backwards the road along which he has trod. I say I conceive it possible to test the fitness of the candidate at one step by one adequate final test. But there are obvious reasons, on which I need not now dwell—reasons pertaining to the economy of time, to the advantages of more continually watching over the wayward student and of early estimating the hopeless ones—in favour of the plan of arranging that the degree should be the final goal of successive examinations at the several stages of study. It will be the duty of the authorities of the new University, when it comes into being, to prepare regulations for its medical as for its other degrees. It is not for me, and even if it were so this is not the occasion, to dwell on the details of the regulations which ought to be adopted. But perhaps I may be allowed to make some general suggestions, to give utterance to some reflections which my experience, now not wholly brief, has borne in upon me.

As I said just now, it has already become impossible to insist by the tests of an examination on the student gaining a knowledge of everything which has a bearing—even a very direct bearing—on the medical art. We must not attempt to make the field of examination conterminous with the field of knowledge; we must restrict the field within narrower limits, and as years go on and science grows more and more the restriction must become more and more decided. The wise man will look ahead and strive not to frame regulations which within a relatively short time circumstances will compel him to mend. Looking ahead, we may be sure that our efforts at restriction can only be conducted along certain lines. Far away in the future it will remain as true as it is to-day, and perhaps appear even more clear, that sound practices must rest on a wise pathology; this in turn on an enlightened biology; this, again, on a firm basis of chemistry and physics. It is not possible to-day, nor will it ever be possible in the future, to lighten the burden of the medical student by throwing out any one of the sciences which in ascending series form the basis of the science of medicine; if you attempt to draw any one of these sciences out and away from among its fellows the educational edifice falls to pieces. Yet it is already absolutely impossible, in view of the expenditure of time and money, to say nothing of brain capacity, that each student on his way to become a doctor should become, in turn, a physicist, a chemist, an anatomist, a physiologist, and even a pathologist. A cutting away must be done within each science, and as time goes on the pruning knife must be used with greater and greater effect. How shall the cutting away be done? There is, I venture, to think, a bad way and a good way.

One way is to pass in review each of the sciences and pick out the bits, the separate facts, and even the disjointed laws or doctrines which are known at the present time to be used in the construction of medical science or in the applications of medical art. We might, for instance, ranging over the wide and varied field of physical science, choose the particular bits—bits of mechanics, bits of hydraulics, bits of electricity, bits of optics, and the like—which the teacher to-day in physiology or in pathology takes for granted as known and acknowledged when he is expounding the solution of a physiological or pathological problem, or which are called into play in the sick room as part of, or guide to, some therapeutic means. And so with the other sciences. We could thus undoubtedly lighten the overloaded medical back. But with what result? I will say nothing of the task of getting these disjointed fragments, held together by no logical ties, deprived of all suggestive connexions, securely lodged in the learner's head—a task of great and disheartening hardness, a task, moreover, which would probably through its repellent difficulties be found to consume well-nigh all the time and energy which the proposed restriction was supposed to save. It will be enough, I cannot help thinking, if I ask the question, Who is to be the authority to decide which bits of this and that science are pertinent to medicine? Who is to pick them out and frame them into a schedule? It will be enough at least if I add the reflection that when we have gathered these various bits together we find them a shifting mass. Each science is for ever changing; new facts are being discovered, new truths are coming to the light. That which to-day is unknown, or if known would be rejected as having no relation to medicine by the builders of a schedule such as I am imagining, may to-morrow become the corner-stone of new medical truths. Were such a schedule in existence few years would pass before the man in active practice would be heard lamenting his misdirected education in which while he was taught much which he now finds to give him no help in his daily life that which he would now find most useful even though then known was left untaught. Moreover, the wheels of the academic machinery which enacts and changes regulations move slowly with much friction. Again and again it would be found that medical theory, and therefore medical practice, was being powerfully swayed by some bit of chemistry or physiology long before the academic authorities had time to insert it in their schedule. Am I not right in saying that this is a bad way?

But there is another way. From time to time the man of

Digitized by Google

science is, according to his mood, pained or amused at a man of letters of repute or even of eminence—a poet, a historian, or a novelist—delivering himself upon a difficult, disputed question of science. The man of letters may be acute and logical, may have diligently studied the special facts bearing on the problem; and yet to the man of science his conclusions merely raise a smile or a sigh: they are so preposterous and obviously wrong that they will not bear for a moment the test of rigid scientific scrutiny. So again, within a narrower circle the physicist or the chemist from time to time flounders conspicuously when he attempts to solve biological problems; the biologist when he pronounces judgment on physical or chemical theories; and either of them when he delivers himself of his views on questions of abstract philosophy. And that though each in his treatment of the subject may show talent, acumen, and knowledge. There have been instances to the contrary, but it is this which often happens. A master in one branch of learning, if he attempts to go beyond the tether of his accustomed thinking, is apt to expose himself to defeat at the hands of a mere disciple. For each kind of learning, each branch of science, has what may be called its own way of thinking. Different phenomena observed by different methods, different ideas born in different ways, different devices for overcoming different obstacles, all these go to create different attitudes of mind and different modes of laying hold of truth. Not until the mind has been accustomed to watching the phenomena which constitute the subject of a branch of science, not until have been learnt by practice the ways in which in the past the problems presented by these phenomena have been solved, is it ripe for the attack on problems yet to be solved or for critical judgment on solutions of those problems offered by others. This is at once the only real and the royal road to learning a science, getting to be able to think in it, to grasp the ideas which form the body of it in such a way as to be able if opportunity offers to add to it new consonant ideas, or at least to judge truly new ideas offered as being so consonant. This is the kind of learning which the doctor wants. His life is, on one side of it, one prolonged investigation—not a continued inquiry into one homogeneous problem, but a repetition of attempts to solve the multitude of diverse problems presented to him day by day. His success, on this side of his life at least, will depend on his power of right thinking; and his power of clinical thinking is in part the outcome of his being trained to think in other things. He needs to be trained to think in physics and in chemistry in order that he may use these sciences aright when he attempts to study biological or physiological problems. He needs to be trained to think in physiology in order that he may think aright in pathology, and so, with his feet set in the right path, may in his future life be able, through the instincts as it were of a well-ordered mind, to recognise swiftly the value of the right views and the worthlessness of the wrong views which from time to time will be offered to him touching the nature and causes of disease. It is not the facts of physics, of chemistry, and of physiology which form the most important part of the medical man's training during his novitiate of study (the facts of anatomy stand on quite a different footing); it is the right way of viewing these facts, the right way of thinking about them, which is the essential need. If the mind be put in the right way the facts can be gathered up and put in their proper place at any time, even in late after-life. But the mind can be fixed aright only in the early years of training.

Here I think I hear some one say: "I thought you were proposing to lighten the burdens of the medical student; surely it is not a blessing but the reverse which, if I rightly understand you, you are now offering to him. We are groaning under the heavy burden of having to compel the student to study those sciences auxiliary to medicine; we hitherto have been content that he should know; you are proposing that he should not only know but understand. Do you call this a help?" Yes, much help every way, but only on two conditions touching the way in which the affairs of a university are conducted. The first condition is that the authorities to whom is entrusted the appointment of the teacher, professor—call him what you will—of each of these sciences, should recognise in the selection of the holder and in the award of the emoluments of the chair, and that the teacher himself should recognise, that the office is one not of teaching only, not of didactic exposition only, but of learning, of inquiry and research. I know very well that the gift of investigation and the gift of facile exposition do not always—possibly do not often—go hand in hand. But the power of thinking in a science on which I have been dwelling is not taken in as drops falling softly from the lips of the teacher into the open mouths of the passively recipient hearer; it has to be gained by the exertions of the learner and largely by active work in the laboratory, and I never heard of any-one having in him the true spirit of inquiry who in the quiet studies of the laboratory failed to carry his pupils with him onward from truth to truth, however sorry a figure he might cut when he attempted in a formal manner to thump the professorial pulpit. On the other hand, if the spirit of inquiry be lacking an exposition clear as crystal, aided by elaborate diagrams or a projection lantern, while it seems to be wholly luminous may leave the mind of the hearer really dark. The art of teaching in the true sense of the word is not the art of pouring into empty vessels; it is the art of awakening latent powers, the art of nursing that feeble infant the desire to know, until, growing strong in limb, it is able to walk alone and go on its own way. The only teacher who can truly teach is one who is himself bent on going forward, to whom each bit of new knowledge which comes before him is not something to be stuck in its proper place in the catalogue of things known, but a stepping-stone from which to make a new stride. The second condition is that the tests, trials, examinations—call them what you will—by which the progress of the student is measured should be directed to appraising his intellectual growth, not his accumulated knowledge; to determining how far he has got on the road, not the amount of luggage he has gathered on the way. This cannot be achieved solely by means of one or two trials of written questions and answers, even with the aid of a string of manipulative puzzles, often called a practical examination. By hypothesis we are striving to lighten the burdens of the medical student; we are desiring to find out the minimum of knowledge of any one science, say physics, possessing which he may be permitted to pass on to the study of the other sciences based on that. I am arguing that it will be enough if we can be assured that he has learnt to think in physics, that he has grasped the methods of physical inquiry to such an extent that when in some other science—in pathology, for instance—a problem is treated by physical methods he can comprehend that treatment. No stranger examiner, even though he had the skill of an angel, could gain that assurance by merely shooting questions at the student on one or two formal occasions. One person only is in a position to form a judgment on the matter, the teacher who has really taught the student, who has brought him on his way not by formal lectures only, useful as these are in their proper place, but by frequent intercourse in the laboratory, watching him at his repeated exercises, sounding again and again by quiet talks the stream of his thoughts. He alone is in a position to say that which we are supposing is all that need be said—that such and such an one understands what he has been taught and may now safely pass on to other studies. If it be feared that such a judgment is a responsibility too great to be laid on the shoulders of one person, seeing how personal predilections or other motives might come in to warp it (though in a well-ordered mind and a well-ordered university loyalty to the science on the one hand and to the university on the other ought to be a safeguard strong enough to render such a fear of little moment), let his results be checked by someone else and the student's fitness be declared by the mouth of two witnesses of his work. But, so far as I can see, it is only by taking the teacher into full confidence and making large use of him that we can hope so to adjust the increasing demands of the sciences auxiliary to medicine to the fixed and stationary capacities and opportunities of the student as to train up men in such a way that their purely scientific studies shall be wholly a help to, and not at all a drag upon, their strictly professional learning.

Here it may be said: "This proposal to lessen in the case of the medical student the demands on the auxiliary sciences will bear hard upon the teacher. It lessens the time to be given up to each science and so virtually lessens the number of the teacher's students and his fees, while at the same time it increases the labour which he spends on each student; moreover, it cuts away, as far as the medical student is concerned, the higher teaching of science. The

Digitized by Google

life of the teacher is a hard struggle as it is. If the artificial props by which he is supported be taken away he will fall to the ground." Here comes in the idea of the university. A university is not an educational institution directed by the principle of "payment on results." It does not set itself up as a rival to a system of classes which proposes at the least expenditure of time, money, and, it may be added, of brains to drive a head through the same narrow gateway of this or that formal examination. The one reason for its existence is the encouragement of learning, and that irrespectively of the immediate benefits of new truths. It is because it works for ends the good of which may not be seen at once that it cannot be conducted as a "paying concern." If it is to flourish it must not be expected to live from hand to mouth, its livelihood must be assured to it by the gifts of its friends or, failing that, by the aid of the State. As the university looks to be treated by the world, so it must treat those who do its work. Since it lives for the advancement of knowledge, it must see to it that the men who are for the time being its flesh and bones are placed in circumstances as far as possible favourable for their doing their best to push forward the limits of the known. Part of these men's work is, as we have seen, available for immediate use, and as such may be duly appraised; but the value of much of it lies hidden in the future. It is just this uncertain moiety which needs the most kindly care. The worth of a university is to be measured not alone by the number and quality of the graduates which it turns out into the world, but also, and even more so, by the number and quality of the new truths which go out into the world from its laboratories and lecture rooms; by its work of research will it in the end be judged. Research grows on leisure and quiet; only in rare cases will it flourish in the midst of turmoil and with the wolf crying at the door. By all means, as I have already urged, let teaching and learning stand side by side; bid the teacher investigate and the investigator teach; but let the teaching be so ordered and so rewarded that the teacher has ample time and repose for his research, and, content with his line, is placed beyond the temptation of giving up to the search for gold the time and energy which ought to be spent in the pursuit of truth.

You here, in Birmingham, have a great opportunity before you. You are not trammelled by historic bonds, or by vested interests, or by ties of the State. You are free to mould your new University as your judgment directs. May I bid you not to copy slavishly the outward lines of any model, old or new? Do not attempt to wear the clothes of the old universities, the fashion of which has been determined by a past which you have not. Do not be led to think that when you have spread a net of examinations you have built a lasting house. Let the spirit of inquiry be your guiding spirit; you shall find that as you follow it other things will come in its wake. If your teachers be men busy garnering new truths, their pupils will gain real knowledge. With such teachers and such pupils you may safely throw aside many of the present devices, at once irksome and insufficient, for testing the work of the scholar. You will be able to afford to make your degrees at once efficient and economical, inasmuch as they will be remunerative not merely by the possession of them, but in the very getting of them. If you do this it will be strange if you do not reap the reward not of honour alone, but also of material success.

I fear that I may have been preaching heresy and that in many things which I have said I have been very bold, but I have been encouraged to think that I might speak freely in a place which in times past and in other things has shown that it is not afraid of leading the way. One word more and I have done. I have been speaking this evening chiefly of matters medical and have been urging the claims of scientific development, but I would not wish to be thought the advocate of science alone. Though it is true that the term "university" does not mean the care of universal knowledge it is equally true that the full good which a university may gain cannot be gained if it narrows itself to one line or even to a few lines of study. For each branch of learning nothing is so good as to be continually in touch with other branches. The ideal university is that to which whosoever comes finds what he wants to learn, whatever it be. May I hope that your university, when it comes, will draw near to the ideal, that it will set itself to nurse every kind of learning, disdaining no kind of knowledge because it seems useless, being afraid of no kind of knowledge because it is openly, even glaringly, useful.

ST. GEORGE'S HOSPITAL.

INTRODUCTORY ADDRESS BY MR. G. R. TURNER, F.R.C.S. ENG., SURGEON TO THE HOSPITAL, ON "THE VALUE OF MEDICAL WORK TO THE COMMUNITY AND ITS INADEQUATE PECUNIARY REWARD."

AFTER some introductory remarks, in which allusion was made to the deaths of Dr. Wadham and Mr. Henry Lee of the consulting staff, and that of Dr. Leonard Remfry of the acting staff, of St. George's Hospital, it was pointed out that education for the medical profession demanded now an industry on the part of the conscientious student greater, perhaps, than that required by any other vocation but which was well repaid by the greater interest of the study. "Walking the hospitals" necessitated of the modern student the attendance on more than 1000 lectures and demonstrations during five years quite apart from his purely hospital work. In a review of the past St. George's Hospital year reference was made to the recently published "Life of Sir Benjamin Brodie," an old surgeon of the hospital, by Mr. Holmes, the treasurer. The extreme value of a medical treasurer who had already spent many years of his life on the honorary staff was insisted upon and for the benefit of hospitals such appointments should be more frequently seen. A review of the athletic achievements of the St. George's Hospital students for the past twenty-five years showed of what stuff the modern medical student was made. This comparatively small school had produced amateur champions in running, rowing, boxing, cycling, cricketers who had played for their counties, many university oarsmen and runners, international football players, a lawn-tennis champion, and authors of books on mountaineering, skating and cycling. More than natural aptitude and physical development is wanted for such athletic success; self-denial, self-restraint, perseverance, and patience must accompany these—qualities the public are not wont to credit the medical student in his lighter hours with, but which he possesses to a marked degree. His work, too, has a distinct pecuniary value; it saves his hospital the employment of extra staff and nurses and in this work he may have opportunities of showing disregard of danger, devotion to duty, and self-sacrifice. The courage of the medical man is tested without accompaniment of the skirl of the bagpipe or the beat of drum, but it may equal that of the soldier. In his struggle with disease no publicity awaits the wounds he may receive, his life he may lay down in doing his duty, and those near and dear to him are too often left in poverty with no grateful country to provide for them. Save to a very few honoured with the rank Sir Gorgius Midas accepted with indignation as that given to a successful sawbones there comes no rank, no title, no distinction to mark the experienced veteran from the latest recruit. The medical student, so amusingly and graphically portrayed by Dickens and Thackeray, has too long been taken by the public to be typical of a low fastness, uneducated, unclean, redeemed only by the saving grace of humour and a love of practical jokes. The worst types of a bygone age, when anyone who chose could call himself a medical student, have led in the past to this conception of him. To-day students are largely recruited from public school and university men. At Cambridge alone in the last ten years 9437 undergraduates have matriculated. No less than 1253 are registered students of medicine—more than 13·2 per cent., nearly one in every seven—a splendid tribute this to the work done by the late Sir George Humphry. At Oxford in nine years but 212 undergraduates out of 7330 have elected to follow medicine. This number, now that the claims of science are to be more recognised there, will doubtless be materially increased. The behaviour of the 3000 London medical students compares not unfavourably with that of the admittedly well-behaved undergraduates of Oxford and Cambridge who have less temptation and more restraint. Not only Dickens and Thackeray have been hard on the medical student, but Tennyson in his poem, "In the Children's Hospital," has been unfair to surgery. Thousands have read the poem and pictured the surgeon; very few are aware that Tennyson expressed to the late Sir Andrew Clark his regret that he ever wrote it. The writings of Molière, like those of Dickens, Thackeray, and Tennyson, live after him, and careless readers may forget that the medical men whose pretentious ignorance he ridicules were those of 240 years ago, who had the ignorant confidence of empiricism combined with a fatal activity of treatment, now happily absent. To live down the writings of such masters of literature would have been a hard task for any

Digitized by Google

class of students for any profession; the medical one is now very fit for any one with high ideals, good health, good intellect, and a capacity for hard work. It is as philanthropic as the clerical profession, but receives less State and social recognition. Surely the fascination of scientific study should attract more of the intelligent well-to-do than it does. By the triumphs of preventive medicine, hygiene, and sanitary science the overstocked medical profession is rightly and honourably doing all it can to prevent work for itself. This unselfish action is too often misunderstood and medical men are said to "have fads" and are suspected of furthering instead of standing in the way of their own interests. The profession is infested by quacks, forestalled by prescribing chemists, sweated by clubs and medical aid associations, and the hospitals which are so largely gratuitously served by its members lend themselves, however careful may be their supervision, to an abuse which diverts many a fee from the struggling practitioner. In London alone nearly 17,000 maternity cases are treated at the general hospitals, more than 1,200,000 out-patients and casualty cases and nearly 70,000 in-patients. Here must be an enormous number of unsuitable cases for charity at the expense of the involuntary philanthropist, the general practitioner. No wonder that the building of a hospital in a new locality is regarded by him with very mixed feelings. We of the profession know these things, for are they not written every week in our chronicles? Has not everyone with experience been a personal sufferer? The public, however, who subscribe to the various Hospital Saturdays and Sundays, to royal, emergency, and other funds; the public who by their liberality and legacies have hitherto prevented the institution of State-aided hospitals and their inmates being a burden on the rates—that liberal public which supports by voluntary contributions 23,204 beds in the 716 hospitals of the British Isles on which more than one and a half millions of pounds sterling (£1,629,114) is spent annually, is it aware of what "the doctors" do? Not only are there 716 hospitals, but dispensaries and convalescent homes swell the number to 1155 institutions, spending nearly three millions of pounds a year (£2,825,376).

The immortal Darwin, by means of the brightness of his genius and patient research, first threw light on the dark places of the earthworm, showed how ceaseless is the good, silent work that the lowly, humble creature does, how greatly vegetable and animal life are indebted to it. Sir Henry Burdett, to whose great statistical work on hospitals and charities I am indebted for the figures I have quoted, has made himself a benefactor to the medical profession by the mere enumeration of its ill-rewarded labours in all the centres, in all the out-of-the-way dark corners of the United Kingdom, wherever there is suffering, wherever there is poverty or distress, wherever, in short, there must be medical charity. He has done much by compiling statistics to tell of the ubiquity of medical gratuitous labour, the unlimited potentiality of the poor and others who are not poor, and should be ashamed to pauperise themselves to command the best advice in their neighbourhood. In London alone there are, I find, 7540 hospital beds and 14,597 in Poor-law infirmaries, making 22,137 beds for the poor man and his family. Something has been done by Sir Henry Burdett to show how the medical labourer is rewarded, but statistical tables on this last point are almost necessarily absent. I have made inquiries at the various general hospitals in London, numbering some 24, and having an annual expenditure of £487,248—nearly half a million. Of this amount I find that there is paid to medical men, resident and non-resident—there being in all some 165 resident and 466 non-resident appointments—a total sum of under £13,000, that is to say, 2·66, a little more than 2½ per cent., of the whole amount. An analysis of these payments at hospitals with medical schools attached to them shows that there are 256 unpaid and 170 paid medical officers. Were it not that one institution pays every one of its 64 officers this proportion of the (inadequately) paid to the unpaid would be much less; thus 11 hospitals have 256 unpaid officers and they pay only 106. They expend £6890 annually in doing this at an average of £65 to each paid officer. Curiously enough, the average of payment at St. Bartholomew's Hospital, paying £4188 to its 64 officers, is also just over £65 a head; but there all are paid something. The payment even when existing is admittedly inadequate; hard work of from three to six hours a day requiring a highly qualified, trained, skilled man to do it is rewarded perhaps by £50 a year—such, for instance, is the work of a registrar. Only 4 hospitals pay anything to their visiting staff. The other 8 hospitals pay only 38 out of their 240 officers. The total expenditure of these hospitals with their medical schools is £392,488 per annum—£11,078 pays their 426 medical officers. Probably hospitals with no schools attached are even less generous to their medical staff. The truss and surgical aid societies expend £20,492, paying their medical officers as far as I have been able to ascertain £850. I do not say that it is wrong that so little should be given for so much—that hospitals are so literally *medical* charities—but I do say without fear of contradiction that such pecuniary facts as I have collected are not generally known by the public and that were they known and taken as a type of what our profession—the only one save the clerical profession that habitually and constantly gives its services for practically nothing—does, I say that that profession would be more widely respected, more esteemed, more honoured, and have more social consideration shown to it than it has at present. Those in authority and power might possibly not only compliment us on our noble calling, but by occasionally actually ennobling our really scientific leaders give a bench of bishops and distinguished law lords suitable companions in that Upper House where now Lord Lister sits alone. Who could be a more worthy representative and more typical of the profession at its best than this man, who has already by his practical application of the discoveries of science restored the health of more people and saved more lives than the greatest warrior lord of any time has ever crippled or destroyed?

These pecuniary facts are not generally known by the subscribing public nor is the enormous private charity of even the poorest general practitioner. Hospital service is more onerous, demands more time, and is not now indirectly paid for as much as formerly, nor is there much profit to the teacher from medical education. So-called "pay hospitals" are too often patronised by the comparatively rich and the pay is diverted from the medical man. This state of things is not confined to England. Dr. Wiggin of New York, in a paper on the existing abuse of medical charity, considers that it is established that not far from 50 per cent. of all applicants for free medical relief in the larger cities of America are not persons who require it. The cult of altruism is a luxury getting beyond the means of the ordinary member of the medical profession, and well might the medical man with an execution in prospect paraphrase Madame Roland and say: "O Charity, what things are done in thy name." There has come a time when this charity is no longer requested but demanded of him, sometimes by locally powerful organisations, such as clubs and friendly societies. It is his duty to his medical posterity to resist this and to see that an abuse admitted by all is not allowed to spread.

How would the great profession of the law regard the erection of suitable law-courts by public subscription all over the country, the payment of all engaged therein save solicitors, counsel, and judges, the unpaid to wait for years before being allowed to practise to show their capacity, being liable if thought or found incapable to lose their reputation and to be cast in damages to be paid to the pauper and other litigants, the reward of the successful few being a private practice elsewhere, and even those who succeeded to still give their services in the gratuitous courts? What is done all over the kingdom by the medical profession, not by any means a rich body of men, and which I am far from saying is wrongly done by them, seems Gilbertian and grotesque when applied to any other profession, save perhaps only the clerical. In the latter, however, there are Lord Archbishops, one of whom takes precedence of all but the blood royal, there are lawn-sleeved bishops in the Lords, there are plums and palaces, and the clergyman, poor though his stipend and emoluments may be, humble, too, perhaps his origin, is received into rural and city society because of his profession, where his brother philanthropist, the modern missionary, the medical man, is often excluded because of his.

The medical profession must be militant also and militant not only against disease. Too long has sufferance been the badge of all our tribe. The world is governed by sentiment, not by science, and sentiment, her appetite growing by what she feeds upon, demands rather than asks for gratuitous scientific service. Many laymen resemble the old lady who was so much moved by the sermon that she borrowed from her neighbour a sovereign, not perhaps ever returned, to put into the plate which was presented for her charity.

Digitized by Google

The profession has too long been lending that sovereign and on too many days of the week, the old lady partaking meanwhile of the satisfaction born of good works, the good work of using the services of another.

So-called hospital scandals, where sometimes the committee and sometimes the medical officers have erred, and sometimes erred together, usually seem to end in resignation of the medical and the continuance in office of the lay element; the medical scapegoat is brought to the door of the tabernacle, has the sins of the people laid on him, and is sent away with his burden into the wilderness. Would this scapegoat be found so often in our ranks were they firmer, more animated by *esprit de corps*, more determined to stand shoulder to shoulder and to resist to the last? It is a great thing and conduces to peace to be known to be ready, if necessary, with the pistol. *Noli me tangere* should sometimes be a medical motto, and any one of us or any body of us justly struggling for some right should be able to be sure that whatever the result there will be no underselling, no supplanting by those from whom moral support at least should come—the medical profession. That this is not so is one of the sources of our weakness, one of the reasons of the rarity of successful resistance, one of our obvious faults. Such resistance should not be limited to those immediately concerned, but should be supported, led, and if need be initiated by the well-to-do and prosperous of a profession too often and in too many places unable to assert itself because of its very numbers, its keen competition, and its poverty induced thereby.

The methods and manners of trade unions are to be deprecated. The profession is admittedly something nobler than a trade; but medical charity has outgrown its proper limits and its further extension and multiplication will kill what little independence remains in a sorely tried profession. We must all be in some sense dependent; none can be absolutely free; but there is a servile dependence ignoble and dishonourable as there is a dependence which is honourable, right, and worthy of the labourer, as he himself is worthy of his hire; a dependence worthy of a profession at all times and in all places ready to give its services to the really poor and needy in all walks and ranks of life; a dependence which will still allow of the maintenance of that which should belong to all of us and is the due of each member of an honourable calling—self-respect.

ST. MARY'S HOSPITAL.

INTRODUCTORY ADDRESS BY DR. H. A. CALEY, PHYSICIAN TO OUT-PATIENTS AT THE HOSPITAL, ON "PREVENTION IN MEDICINE: THE NEED FOR A FORWARD MOVEMENT."

GENTLEMEN,—Instead of more abstract advice I invite your attention to-day to one single principle, which by virtue of its intrinsic importance as a moulding force and its far-reaching beneficial results in practical operation has had so much to do with the triumphs of medicine and surgery. I refer to the principle of Prevention. My chief aim is to emphasise the need for a forward movement in applying this principle of prevention, and by way of illustration I shall, as far as possible, refer to matters of current interest or which have attracted attention during the past few months. Our knowledge of the causation and processes of disease is to-day such as it has never been before, hence never was there a time more opportune than the present for increased attention to this subject of preventive medicine—using the term in its most comprehensive sense. The occasion is likewise opportune in that the formal opening of the Winter Session is one of the very few occasions upon which we have the opportunity of expressing our views in the presence of representatives of the non-medical public, without whose intelligent and energetic coöperation this great principle can never have free course or produce its full results. I anticipate the criticism that this subject would be more appropriate for an address introductory to practice than for an address introductory to the student's medical curriculum—for the fifth-year student rather than the first-year student. The fact remains that there is but one such address, and it is my firm conviction that the earlier the student appreciates the responsibilities which the practice of medicine involves, and the range of influence which may one day be his, the more intense and earnest will be his interest in the successive phases of that course of study and experience which are designed to fit him for a life-long conflict with disease and death.

Owing to the restricted and specialised sense in which preventive medicine is frequently regarded I fear that this aspect of medical work does not receive due attention. To cope with preventable disease is regarded too much as the business of those who devote themselves to public health work and too little as the concern of every practitioner of medicine, still less as that of the community. It is not, however, by the foresight and expert knowledge of the few, but by the energetic coöperation of the many, acting under the guidance of expert knowledge, that a decisive blow can be struck against the forces of preventable disease. Whilst we look for and work for fuller light and more perfect knowledge it is unquestionably the fact that vast results in the prevention of disease are within reach, if we could but persuade men to act up to the light they already possess. In the popular conception of preventive medicine in this country no disease occupies a more prominent place than typhoid fever. It is a matter of common knowledge that sudden epidemic outbreaks of typhoid fever are most commonly due to water-borne infection, and next most commonly to milk-borne infection, and that consequently the surest means of prevention against such outbreaks is purity of water-supply and of milk-supply, whether that purity be due to absolute purity of source or be induced by efficient sterilisation.

On the basis of these simple facts much has been done to prevent epidemic outbreaks of this disease; how much yet remains to be done the events of the last twelve months can testify. Epidemics such as those which have so recently involved the sacrifice of hundreds of lives, incalculable suffering, and great material loss are essentially preventable if local authorities, communities, and individuals would but do their duty in the sanitary sense—a high and costly standard of duty it may be, attainable it certainly is. Whilst, however, we can speak confidently of purity of water-supply and of milk-supply combined with efficient sanitation as certain preventives of most epidemic outbreaks, we have to recognise that the origin and therefore the prevention of some of the comparatively isolated cases, of limited and recurrent outbreaks, or of the more or less persistent prevalence of the disease in certain localities, is by no means so clear. To Sir William Broadbent, in the first instance, we owe the explanation of the origin of some of these cases—conveyance of typhoid infection by specifically contaminated oysters, and the relation of shellfish to typhoid fever infection has rightly attracted much attention. But there are in this country districts, towns, and even dwellings where enteric fever repeatedly occurs or is rarely entirely absent. During the past year evidence has been accumulating in favour of the view that organically polluted soil by favouring the persistence in more or less active form of the typhoid organism has much to do with the tenacity of typhoid fever in such localities—a view to which Sir Richard Thorne gives prominence in the last report of the Medical Department of the Local Government Board. The researches recently undertaken by Dr. Sidney Martin, at the instance of Sir Richard Thorne, certainly demonstrate that the condition of the soil is of prime importance in modifying the vegetative activity of the bacillus typhosus. Dr. Martin finds that in certain samples of organically polluted soil the bacillus is capable, not only of retaining its vitality for as long a period as seven or nine months, but also of multiplying and permeating the adjacent soil, whereas with virgin soils no sign of vitality could be discovered as the result of testings 14, 20, and 23 days after inoculation. These and other experimental observations warrant the inference that "whilst one soil and set of circumstances are highly favourable to the vitality and propagation of the typhoid bacillus, another soil and set of circumstances are rapidly destructive to it." Striking collateral evidence which tells in the same direction is afforded by a study of the topographical distribution of typhoid fever. It is remarkable that whilst the disease has been undergoing enormous diminution in this country, the areas of both its maximum and minimum incidences have remained practically the same during the 20 years 1871-90, and further that much of the persistence of the disease is associated with those sanitary conditions which involve organic pollution of the soil.

The bearing of such considerations as these on prophylaxis is obvious, having reference not so much to

Digitized by Google

direct channels of infection as to the conditions of environment which are most favourable to the vitality and multiplication of the organism of the disease. It is of interest to note in passing that energetic preventive measures may prove their efficacy long before their precise *modus operandi* is known. The introduction of impermeable pavings in yards about small cottages and tenement properties in towns and the prevention of soil contamination were measures of proved efficacy before any such explanation as that now suggested was forthcoming. My last words on the subject are to direct attention to the necessity for more reliable and rigid disinfection in the management of individual cases of typhoid fever. It has for a long time past appeared to me that there is very great danger from partial or perfunctory disinfection, and quite recently attention has been directed to the subject by Dr. Franklin Parsons of the Local Government Board and also by Dr. Robertson, medical officer of health of Sheffield.

In face of the officially expressed opinion of the medical adviser of the Local Government Board that the death-rate of this "typically preventable disease" would seem to be coming to a standstill we are bound to advocate a fresh forward movement towards the eradication of the disease. To be successful it must be comprehensive and take account, not only of infected water, milk, and other articles of diet, but also of factors of another kind, the influence of soil and other circumstances on the vitality and multiplication of the typhoid organism, the dangers of lax disinfection, and, under certain circumstances, of infected dust also. Did time permit we might refer to what has been accomplished in the prevention of cholera or to the vast and practically new field for preventive medicine which the study of tropical diseases is opening out. What possibilities as to the prophylaxis of malaria—that great barrier to civilisation and colonisation—are suggested by Major Ross's recent observations on the relation of the mosquito to the malarial parasite.

Preventive medicine in the field of tropical disease is of national importance to this country with its world-wide empire, and the recent decision of the Colonial Office to send out in conjunction with the Royal Society a Commission to investigate the dissemination and prevalence of malaria shows that this is now appreciated in the highest quarters. On this occasion it is impossible not to digress for a moment to express our appreciation of what foresight and efficient organisation have accomplished in the medical arrangements of the Soudan campaign, recently so brilliantly concluded. The newly constituted Royal Army Medical Corps had not long to wait before it received its baptism of fire at the battle of Khartoum, and I feel sure that I express the unanimous opinion of my colleagues in saying that we hope that many of our present students will elect to serve their Queen and country in the Royal Army Medical Corps as well as in the Naval and Indian Medical Services. Since October of last year the whole aspect of affairs in regard to the Medical Department of Her Majesty's army has changed, thanks to the Marquis of Lansdowne and those associated with him in this great reform. There is now every reason why some of the best of our students—the best all round men—should be proud to serve in the Royal Army Medical Corps.

To return, if much yet remains to be done to prevent typhoid and other infectious fevers, what shall be said of that essentially preventable but far more disastrous disease, tuberculosis, which is still allowed to a large extent to run riot in our midst? So long as phthisis was regarded as "constitutional," due to a special diathesis, as an hereditary disease, or among the misfortunes incidental to particular climatic conditions, an attitude of hopeless indifference as to its prevalence was perhaps intelligible. But with the knowledge that tuberculosis in its varied forms and diverse manifestations is a specific and infective disease—i.e., that it cannot arise *de novo* or from accidental causes, but only from the infection of and development within the body of the specific organism of the disease—a policy of inaction is indefensible and active measures for combating its prevalence are imperative. Long before Koch's memorable discovery of the bacillus tuberculosis in 1882 far-seeing workers in preventive medicine had initiated hygienic measures of the utmost importance which have done much to reduce the mortality from phthisis in this country. During the last fifty years the deaths from all forms of tuberculosis have diminished by about 40 per cent. and the death-rat from tuberculosis of the lungs alone much more than that; but when it is remembered that the number of deaths per annum due to various forms of tuberculosis is between 50,000 and 60,000 the necessity for grappling with this problem is clear.

That further advance is called for in the direction of improved general hygiene is evident not only when we consider the substantial successes already secured, but equally so in view of the established fact that the incidence of human tuberculosis is intimately connected with insufficient or impure air, deficient sunlight, overcrowding, insanitary houses, damp subsoil, and other hygienic defects—conditions which are especially to be found in densely populated cities. Much has of recent years been done by owners of property and employers of labour to improve the conditions of life for those of the lower classes, much more might have been done had not avarice been at times allowed to stifle philanthropy. I cannot say that I agree with the opinion expressed by some that the limit of progress in the direction of improved hygiene has been nearly reached, but I do say most emphatically that a campaign for the repression of tuberculosis will not meet with success unless the attack is developed and pushed forward in other directions. In my judgment, one great bar to progress at the present time is the inadequate recognition of the essentially infective nature of tuberculosis. Not that tuberculosis is, in the popular sense of the word, infectious, so that those who come in contact with the victims of phthisis are to be in dread of contracting the disease, but infective in the sense that the disease cannot exist in the absence of the specific organism of the disease, however strong the predisposition to it may be. The first step in advance is the practical recognition that by the adoption of systematic measures to destroy or limit the dissemination of the specific organisms on the one hand and to remove associated factors and predisposing causes which favour its prevalence on the other the prevention of tuberculosis is actually attainable.

The relation of phthisis to climate is still much misunderstood. The fact is, that though influenced by climate it is to a very large extent independent of it, being practically an ubiquitous malady but closely connected with aggregations of the population. Where people are aggregated together in imperfectly lighted, badly ventilated, and insanitary houses, there tuberculosis is rampant, whilst a population which can live a healthy open-air life enjoys comparative immunity. It has been shown by Ransome, Cornet, and others that even in the same town there may be local "infected areas" or even "infected houses," notorious for their persistent phthisis mortality.

Much has of recent years been done towards the adoption of systematic measures for disinfection in the management of phthisical patients, which is the very starting-point of efficient prophylaxis, as yet but little towards disinfecting rooms, dwellings, and belongings which may harbour and maintain in a state of latent activity the deadly germs of the disease. Important to all, this is doubly so to delicate or predisposed subjects and should never be lost sight of in the selection and preparation of dwelling houses. Measures to ensure efficient cleansing and free resort to nature's own disinfectants—fresh air, air in motion, and sunshine—should always be employed wherever tuberculosis is or has been. In this matter of disinfection we are far behind some other countries; for example, Italy and France. I note that at the French Tuberculosis Congress, held in July last, M. Martin stated that, whereas in 1892 only 4000 dwellings tenanted by tuberculous patients in Paris had been disinfected, in the first six months of 1898 no less than 7000 had been dealt with. Some of the speakers at this Congress severely criticised the apathy of the medical profession in the matter of an aggressive movement against tuberculosis. Can we say that the members of the profession on this side of the channel are as enthusiastic as the situation demands? We certainly cannot hope to cope with the almost absolute apathy of a large section of the public if there is relative apathy on our part.

The danger, more especially to children, of infected milk is now widely recognised and the Report of the Royal Commission on Tuberculosis, issued this year, has given prominence to the extent of the danger by laying stress upon the extraordinary virulence which such infected milk may possess. Fortunate as it is that sterilisation by boiling is so reliable a safeguard, the aim of the future must be to secure an uncontaminated milk-supply to start with, and it is to be hoped that the Government will in the near future take steps to carry out the recommendations of the Commission as to dairies and dairy stock, matters in which we

Digitized by Google

are far behind some of our continental neighbours and colonial *confrères*. The danger from meat has, as the Commissioners point out, been much over-estimated, and it seems clear that it could be reduced to insignificant proportions by provision for systematic meat inspection by properly qualified inspectors—a matter urgently requiring the attention of the public authorities. It is not a little surprising to find that this important duty may, under existing conditions, be entrusted to carpenters, bricklayers, plumbers, or stonemasons—a state of affairs which will soon be remedied if the recommendations of the Royal Commission are carried out. It is noteworthy that the Commissioners have emphasised that the only way to strike at the root of this matter of food in relation to tuberculosis is to make an organised attempt at the elimination of bovine tuberculosis.

The advisability of making tuberculosis a notifiable disease has been much discussed; no drastic steps in this direction seem practicable or even desirable, but in my opinion regulations for a modified notification, similar to those in force in New York since 1893, might with advantage be adopted in this country, particularly in our large cities. I refer to the regulations of the New York Board of Health, by which the authorities of all public institutions were *required* to notify all cases of pulmonary tuberculosis and all private practitioners were *requested* to do the same, every facility being at the same time afforded for bacteriological examination of tuberculous cases at the public expense, for efficient disinfection by the sanitary authorities and for actual renovation of premises which had been occupied by phthisical patients. Such measures would probably, in time, pave the way for more comprehensive measures, as has been the case in New York. Since last year, 1897, the notification of tuberculosis has become compulsory in that city—a broad distinction being, however, intentionally made between it as a "communicable" disease and the common infectious fevers. The death-rate from all tuberculous diseases in New York has fallen from 4·42 in 1886 to 2·85 it 1897, and, according to Dr. Herman Biggs, who has done so much to bring this about, the present year promises to chronicle a still more decided advance in the same direction.

In any organised attempt to control tuberculosis protection of the healthy and facilities for the efficient treatment of the diseased must go hand in hand. Hence there is a pressing need for the provision in this country of suitable sanatoria for phthisical patients where open-air and dietetic *régime* can be carried out under strict medical supervision and under the most favourable hygienic conditions. That sanatoria for pulmonary tuberculosis are not dependent for their success on particular climatic conditions is evidenced by the diversity of latitude, altitude, and surroundings of many noted sanatoria. It is not only at Davos or at Denver that such success is obtained—Falkenstein, Nordrach, and Goerbersdorf can claim similarly favourable results. If Falkenstein within sight of the chimneys of Frankfort-on-the-Main has accomplished so much, thanks in the first instance to Dettweiler's foresight and administration, why should we not have similar sanatoria in this country? With due care in the selection of sites, the essential requirements of purity of air, a relatively large amount of sunshine, dryness of subsoil, and protection from cold winds, can certainly be fulfilled. In passing we may remark that in many quarters the importance of climate has been over-estimated and that of diet and nutrition under-estimated. This reference to the sanatorium treatment of pulmonary tuberculosis naturally involves the question of the curability of the disease. Contrary to the opinion of a past generation and to the belief, or at least the practice, of many in our own day, we know that whilst the great hope for humanity lies in its prevention, the arrest of tuberculous disease amounting to a practical and permanent cure is a matter of common occurrence. It may be thought that reference to the cure of phthisis is irrelevant to the theme of prevention—as a matter of fact it is but an instance of the successful operation of prevention. Every pathologist knows that it is the rule for the tissues of the body when invaded by tuberculosis to make a definite attempt to overcome the morbid process and to prevent the further inroads of the disease. It is ours to reinforce this natural attempt at cure, and victory or defeat will, other things being equal, turn upon the stage of the conflict at which such aid is forthcoming. Similarly in the case of those who have a predisposition to tuberculosis, inherited or acquired, prevention is everything.

The prevention of tuberculosis is second to none in importance in the whole range of preventive medicine, and the recently constituted Association for the Prevention of Tuberculosis has ample scope for its operations. A well-organised and comprehensive forward movement must soon make an appreciable difference in the ravages of this disease, already steadily declining, and ten years of earnest and sustained effort should mean the saving of tens of thousands of lives.

When one is engaged in urging the necessity for a vigorous forward movement against preventable disease it is not inspiriting to recall that in the case of small-pox the highest executive authorities have within the last three months carried out a "strategic movement to the rear," which has placed the nation in the illogical position of watching a "tremendous" and, as most of us think, uncalled-for "experiment" in a matter of literally vital importance. No doubt moral suasion and the logic of facts would be preferable to compulsion in any form in a community of ideal intelligence and open-mindedness, but with the conspicuous inability on the part of so many to distinguish between the *post hoc* and the *propter hoc* in the matter of the alleged ill-effects of vaccination the prospect is not particularly bright. It is true that owing to the attitude of local authorities the state of affairs as regards vaccination under the previous Act was becoming increasingly unsatisfactory, but surely the rational remedy was not in the direction of the very open door of a "conscience clause." In matters of public health we look to the Government of the country, influenced by the weight of expert evidence, to lead the way in the path of progress, and not to modify its policy in the face of an adverse wave of popular opinion. However, the law being as it is, we must make the most of the good features of the Act of 1898 and, for the time being, concentrate attention on pressing home the true facts of the case respecting vaccination and re-vaccination, so that the number of those availing themselves of the conscience clause shall not be such as to put to the full test the potentialities of this remarkable innovation in public legislation.

Thus far we have for the most part considered instances of the principle of the operation of the prevention in connexion with the group of specific infective diseases, and it is in this field that we see its importance illustrated in the most striking way and on the largest possible scale. But the same principle is also capable of widespread and increasing application in the case of affections of toxic or degenerative origin. The prophylaxis of affections of toxic origin is a wide and complicated subject, which is attracting increasing attention and which is full of promise for the future. Again, many degenerative changes, for example, in the central nervous system which appear to be primary are in reality secondary to infective or toxic processes which either exercise a directly destructive action on the nerve tissue or pave the way for premature decay by initiating that slow process of retrogression which terminates in nervous death, as so ably emphasised by Dr. Clouston in his recent address on the "Neuroses and Psychoses of Decadence." It is not going too far to say that our present-day knowledge of the causation of many of the most formidable diseases of the spinal cord and of the brain brings them within range of a comprehensive preventive medicine. The mention of three all too common examples—locomotor ataxy, general paralysis of the insane, and the neuroses of chronic alcoholism, is sufficient to illustrate this, and may also serve to remind us that in the prevention of disease we must assign due importance to moral as well as to physical agencies. In passing, allusion must be made to the vast influence of alcoholic excess in causing, aggravating, or predisposing to disease. It is difficult to over-estimate the importance of this subject, and to leave it out of account is to surrender an impregnable position in preventive medicine.

One more illustration of the importance of the principle in relation to the preservation of health of the individual will suffice—the application of the principle of prevention to diseases of the heart and circulation. How many deaths due to apoplexy, to angina pectoris, and to other heart affections might be averted or postponed if timely preventive measures were taken to arrest insidious processes which go on unperceived for months or years before they culminate in grave or hopeless conditions? Men are appalled in the presence of a tragic and apparently unavoidable sudden death, or deplore the limitations of the healing art in dealing with the consequences of a paralytic stroke, but for the most part they do not stop to consider that the result might have been very different had an opportunity been afforded for prevention. There is the curious anomaly of a man who periodically visits his dentist every six or twelve

Digitized by Google

months in order that any commencing decay may be detected and arrested before it has gone too far, whilst he considers it quite superfluous to remember that there may be commencing in his person some morbid process, controllable at first, but which if allowed to go on unchecked will in time lead to the arrest of some vital function. In the former instance, where the issue is comparatively a minor one, he applies the principle of prevention, but his attitude is one of *laissez faire* when the heart, the arteries, or some internal organ are at stake. Have you ever thought of the number of lives annually sacrificed prematurely through simple neglect of this great principle? Upon you who to-day embrace the profession of medicine and upon all who practise it this places great responsibility. It is our duty to be ever on the look-out for the first warnings of serious tendencies, not to be content with treating patent derangements of health, but to discover the often less obtrusive indications of potentially grave disease. To the student I would also say—give particular attention to the earliest manifestations of disease, to conditions which are on the borderland between the physiological and the pathological, and to anomalous cases, and—when you know enough—do not be too much fettered by classical types of disease. Again, cultivate a knowledge of perspective in diagnosis and prognosis, do not be content with an array of symptoms and physical signs, however exhaustive, but single out in your mind which are of primary and essential importance and which are but of secondary or incidental significance, then make your diagnosis as accurately as may be, but remember that you must not stop there—the recognition of the true nature of the disease is but a step to ascertaining to what extent and in what precise ways it threatens the physiological integrity of the body.

It is noteworthy and true both of acute and chronic disease that very often danger—preventable danger, too—comes not from the steady advance of the primary malady, but from secondary or incidental development, all the more formidable because unexpected. The basis of what goes by the name of "cure" is very often a series of preventive acts. To a very considerable extent in serious disease our efforts are necessarily limited to warding off threatened dangers incidental to the disease which as such is beyond our control. To use a classical simile, our *rôle* is as that of the pilot—to steer the ship and not quell the storm. That man will best treat a case of typhoid fever or pneumonia who is on the look-out for the first sign of an approaching squall and who navigates accordingly, and the frail bark of a heart embarrassed by valvular disease can only be safely steered by him who realises how to avoid the sunken rocks and cross-currents which threaten to arrest its course.

To some it may appear that the need for prevention will become less with increasing knowledge of specific remedies and more radical treatment. But our clinical experience thus far entirely negatives this and serves to enhance the importance of prevention, though in a somewhat different way. The skilled surgeon may by early operation remove the cause and thus prevent a threatened fatal peritonitis, though the same operation would be of no avail if the peritonitis had fully developed and the efficacy of diphtheria antitoxin in the treatment of diphtheria is in direct proportion to the timeliness of its administration. In each instance the point is to anticipate a further and more formidable development. Instances might be multiplied, but this at least is clear, that in the treatment of disease the principle of prevention is as fundamental as it is in the preservation of the health of the individual, or in the prophylaxis of the plagues of humanity in the aggregate. The community needs to appreciate that in all these three directions there is need for a forward movement—an advance in practice commensurate with the advance in knowledge.

To some of the more junior students the thought will probably occur that at least two years must elapse before they have any opportunity of studying at the bedside the operation of this principle. To such I would say that to recognise without delay its essential importance and far-reaching influence will be to ensure a serious view of your studies from the start. You cannot afford to trifle with any part of your course. The deeper your knowledge of anatomy and physiology the better will be your insight into the facts and laws of life, the only basis of an art of healing which can lay claim to be called scientific, and the deeper your insight into the processes of the healthy organism the better will you be equipped to take your place later as its guardian and protector. You will, I hope, love your work for the work's sake, whether in laboratory, ward, or class room, but it will not be amiss if now and again you pause to ask, What bearing may this have on the prevention of disease? To do this will, if I mistake not, tend towards a deeper and more enthusiastic interest in the work you have in hand; it will ensure your looking beyond the test of examinations to the more searching ordeal of hand-to-hand conflict with disease, and it will also serve to keep before you that unity of purpose which permeates and coördinates every department of your work.

You, gentlemen, who to-day enter the portal of medicine have agreed to take upon you a duty at once noble and responsible. It is no cant to call it noble, because your life work will be to prevent and to relieve the sufferings of your fellow men and one which affords unique opportunities for seeking to consider the interests of others before your own. But let us never forget that the more noble the office the more ignoble does he become who unworthily fills it. With our calling it is true indeed—

> Noble is that's nobly done.

The duty is a responsible one, for the material upon which you work is none other than man himself. The results of our work which we see day by day are enough to impress upon us something of the measure of that responsibility, but we must regard our life-work in yet another and higher light—in the light of a stewardship that has hereafter to be accounted for when we shall have exchanged the "seen and temporal" for "the unseen and eternal." "It is required in stewards that a man be found faithful."

MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS BY DR. ARTHUR VOELCKER, ASSISTANT PHYSICIAN TO THE HOSPITAL, ON "A RIGHT MEDICAL EDUCATION."

Dr. VOELCKER, after mentioning that the introductory lectures afforded opportunities to medical men to give advice to those entering the profession, pointed out that they also enabled the public to learn more of the aims and needs of the profession. Although it was undesirable to dwell too much on the virtues of the medical profession as a whole or to bewail their hardships, it was necessary that the public should ask themselves whether they were doing their duty to the profession. To engage in acts of charity was one of the highest privileges of the profession, but if under this plea medical men were imposed upon and exploited by so-called philanthropists he warned them that the relations of the profession to the public would be placed on a much more business basis in the future. After welcoming the new students on behalf of his colleagues he offered them his congratulations on having chosen a school whose past was the record of the work and lives of some of the greatest ornaments of the profession, whose present bore the impress of growth and the recognition of the necessity for thorough equipment in all the branches of practical and scientific medical study, and whose future was in their own hands. Those who were continuing their medical studies would find additional facilities for work in the new laboratories of anatomy, physiology, pathology, and bacteriology. It was most important to learn how to make use of opportunities, for, as Goethe says:

> "Doch der den Augenblick ergreift,
> Das ist der rechte Mann."

The student of the present day was too apt to expect all his information to be condensed and rendered easily assimilable for him by his teachers, instead of educating his own powers of observation and assimilation. A medical education on such prepared food was very apt to have the same result on the student's mind as artificial food-substitutes too often had on the infant's body. Ruskin recognised this tendency and reproved it. "To be excited for an hour," he wrote, "if possible amused, to get the knowledge it has cost a man half his life to gather, first sweetened up to make it palatable, then kneaded into the smallest possible pills, and to swallow it homœopathically and be wise—it is not to be done." Lectures were unpopular among students, who preferred demonstrations and who claimed that they could read the subject up much better in a text-book, but who forgot that the lecturer was enabled to point out the relative importance of the different facts and could give his hearers the benefit of his personal experience.

Digitized by Google

Attendance on lectures was rightly insisted on, and parents and guardians had a right to expect it. The habit of note-taking should be carefully practised. The demand for increased practical instruction was well justified and the new school buildings of the Middlesex Hospital were an eloquent expression of the recognition of the desirability and necessity of expansion in this direction. When spoken of by some hostile critics as a decaying school, for answer we may point to our new laboratories and ask if these are the sign of decay. Does a dying tree send out fresh branches? Laboratories were absolutely essential for the adequate teaching of the medical man, not only for the acquaintance it gave him with the manipulation of instruments of precision and the habits of observation, but also for the habits of self-help and concentration of his energies. There was a danger lest an unchecked enthusiasm should lead to the encouragement of a fatal faculty for flirtation with work instead of keeping one object in sight at a time. Some short-sighted people have asserted that it was an injustice to the patients of the charity that the Middlesex Hospital should have taken any part in the erection and furnishing of these new buildings, but they forget that the aim and object of all these buildings was to enable those in whose hands the maintenance of the health of the community in the near future will be placed to be thoroughly trained, and just as a well-trained and equipped navy and army were the best guarantees for peace so the hospital was best studying the interests of those it desired to help by providing them with a well-trained and equipped medical force to protect them from and aid them against the onslaughts of disease. In commercial undertakings it has been found advantageous to secure the services of highly-trained scientific men who by their researches in laboratories equipped and maintained at the expense of the proprietors of such undertakings were enabled to give such advice as amply to repay the outlay involved, and in medical undertakings the same would hold good. It was practically impossible for the medical man to live on the return from the pursuit of the purely scientific side of his profession and he should not be asked to devote himself to such work without being offered some return which might at least enable him to pay his way. Medical men were entitled to look to their profession for the earning of their livelihood and if the public only knew what their indebtedness was to those who, often under great disadvantages, work at the scientific side of medicine many would come forward and encourage and render possible the continuance of that work by the endowment of laboratories and lectureships. Laboratories and other increased facilities for work laid the students under increased responsibility for their proper employment. No laboratory or lecture-room alone ever made a good man; they must be used as adjuncts to clinical work and not as substitutes for it. Disease could only be studied at the bedside. Here not only disease but human nature was studied and the medical man learnt how to deal with the people—how to give them confidence and sympathy as well as how to relieve them.

The student should be very careful of the way in which he spoke of medical matters in lay circles. The public were inclined to regard everybody connected with a hospital as a "doctor" and the loose and random talk of an irresponsible student acquired the weight attached to a medical opinion. The public, though much informed, was not well informed on hospital matters and modern sensational journalism while it attracted readers gave them a very false impression of actual facts. It was easy to give a gruesome account of any operation and to mistake calmness for indifference, interest for curiosity, and satisfaction for "gloating," but it was incumbent on the student, both from his sense of loyalty to his hospital and the knowledge of the high aim of the profession he had chosen, to avoid anything which might give those outside any cause to accuse him of callousness, cruelty, or any behaviour unworthy of a gentleman. Besides difficulties connected with work the student had difficulties connected with play. He had to strike the happy mean between the claims of Æsculapius and Hercules. The danger was perhaps greater in the direction of over-work than over-play. The legitimate engagement in any branch of true sport harmed no one; by true sport was meant that the man should engage in it himself and not merely be a hanger-on. In mapping out his work the student should leave a margin, and that a not too small one, for other things than strictly professional work. To allow recreation to usurp the place of work was disloyal to the hospital and dishonourable to those who enabled him to study at the hospital. In sport as in work it was steady, consistent effort which succeeded, and the training of the mind, like that of the body, was a gradual process, too much of either making a man "stale," too little making him "soft." For some sport had no attractions; let them as well as their sporting colleagues cultivate some hobby, something apart from their work which would give relaxation without idleness, and whatever form this hobby took let it be done as well as possible and without interfering with work. The medical student would do well to use his opportunities in London to cultivate his æsthetic tastes, for now was the time when relaxation from work was to be found in recreation and recreation not only in athletics but in the cultivation of the mind. In no profession was it more desirable to resist the all-absorbing interests of professional work. The cultivation of a suitable hobby added years to life, breadth to the mind, health to the body, and pleasure to those around us. These benefits reacted on strictly professional work and enabled it to be done all the better. The student might ask what advantage he was to gain from all this and for answer was reminded of a translation of some lines by Goethe, bidding him "Do thine own task and be therewith content and all beside leave to the Master Power."

UNIVERSITY COLLEGE.

INTRODUCTORY ADDRESS BY MR. SIDNEY SPOKES, M.R.C.S. ENG., L.D.S., R.C.S., DENTAL SURGEON TO THE HOSPITAL, ON "THE PRESENT STATUS OF THE MEDICAL PROFESSION."

[AFTER introductory remarks Mr. Spokes quoted Ruskin that man's proper business in this world falls mainly into three divisions. First, to know themselves and the existing state of things they have to do with. Secondly, to be happy in themselves and in the existing state of things. Thirdly, to mend themselves and the existing state of things as far as either are marred and mendable. Applying these rules to the medical man Mr. Spokes discussed the existing state of things and the status and authority of the profession, and continued:—]

Quite recently we have had an opportunity of observing the value which is placed upon medical authority and expert opinion by the passing of the Vaccination Act. In spite of weighty official representations as to the necessity for vaccination the conscience clause was accepted by both Houses. But the impression left upon one's mind by the discussion was that the majority did not really dispute the value of vaccination, but from some reason or other succumbed to the views of so many of their constituents and boards of guardians throughout the country. Whilst we may express gratification at the protest by the House of Lords, I think we need not on the whole feel too much regret at the new legislation, especially if supplemented by an insistence upon revaccination. Without going into the questions of "the liberty of the subject" and "conscientious objection," one may recollect the unpleasant task it always was to vaccinate the offspring of an unwilling parent. There is still one danger remaining under the new Act which seems to have escaped attention. In spite of improved lymph I venture to prophesy that there will still occur occasional instances of "bad arms." As in the past, certain ignorant mothers will endeavour to rub the lymph away directly the operator's back is turned, and the fact that vaccination is now to be performed in the private dwelling-house instead of at a public station will, in my opinion, conduce quite as much to the introduction of other inoculation than vaccinia. In any case, the antivaccinationists have now provided the nation with a monster experiment upon the living subject which, whilst not needed by the majority, will be none the less interesting to watch from the ratepayer's point of view if from no other.

Let us conclude our brief sketch of the existing state of things by a more pleasing reference to the new Army Regulations for the Medical Service. The number of army surgeons is slightly over 800—too small probably, but their recognition now as something better than "camp followers" reflects honour on the profession to which they belong. The formation by warrant of the Royal Army Medical Corps will do something towards giving the surgeons a proper standing; they have, I believe, a larger proportion of Victoria Crosses than any other arm of the service and will doubtless continue

Digitized by Google

to maintain the high reputation for devotion to duty which army medical men have always held.

Can we, then, take Ruskin's advice and be happy? I think so, but it is of course a question which each will answer for himself. That we are not completely satisfied and content need not make us unhappy. It is said that the happiest man is he with the least ambition and therefore with the fewest disappointments. That is not the kind of happiness the medical profession should enjoy and we may perhaps remember that our text allows us to alter the existing state of things so far as they are "marred and mendable." There is no difficulty in framing a list of needed improvements—one is embarrassed only at having to select examples.

Leaving on one side the question of representation in Parliament and on the General Medical Council, I would suggest that one of the great necessities in the future is a continuance of the struggle to keep the practice of medicine upon professional lines. It is essential that the patient should feel that he is being treated by one whom he may trust to do the best for him with the least possible admixture of the commercial spirit, whose diagnosis, treatment, and prognosis run no chance of being vitiated by any ulterior motives of increased pecuniary gain. With these objects in view it might be well, for instance, that as far as possible the medical man should dispense with dispensing and that the supplying of drugs should be left in the hands of pharmaceutical chemists, who may properly claim by their training to do this work. I know that in some country districts it is impossible and that in some particular cases the patients themselves might prefer the present method. But I think the time has come for the medical practitioner to charge his fee for the actual attendance and skill and not for supplying material. The sweating of medical men by certain medical aid societies is another phase of commercialism for which it must be hoped some remedy can be found.

Passing from this subject one may next notice the existence of unqualified practice by absolutely irresponsible persons which brings much discredit. Nothing short of preventing unregistered persons practising "for gain" is, I am afraid, likely to stop this, and even then unless there is some amendment of the Companies Act there would be an opportunity for escape. Many are not aware that under the present Act an unregistered man who has been successfully prosecuted can proceed with the help of half-a-dozen relations to "turn himself into a company," and as such may legally do exactly the same thing which was illegal for him as an individual. This is perhaps the most "marred and mendable" thing before us, and fortunately there is reason for thinking that the present Government intend to deal with it.

In regard to the question of public health may we not hope that before long a Minister may be charged by Government with full control and responsibility in the conduct of this vast service? By a combination of districts medical officers of health should be appointed as such and debarred from private practice. The work to be properly performed requires special and expert knowledge and training and there are several reasons why the officer should not be in general practice, although some previous experience of that would be an advantage.

The question of coroners' inquiries affords another instance where some change would probably be beneficial. The fact that the jury is impanelled to ascertain the cause of death would surely lead one to think that medical evidence or direction was necessary in every case. A medico-legal coroner is apparently the best for the work and there would be no lack of medical men willing to undergo the necessary amount of legal training if this matter ever receives the attention it deserves.

Time bids me cut short our list of grievances because I wish to close with a few remarks of a more personal nature to old and new students. To the latter I would say: Get rid as soon as possible of the idea that lectures are a waste of time. Do not neglect the auditory pathway by which information can be conveyed. But do not, on the other hand, rely alone upon the lecture; indeed, it is a good plan to read a text-book in advance, and then to take notes of the principal headings of the lecture, to be elaborated afterwards. Study well any graphic illustrations the professor may present by diagrams, and you will, by a combination of ear, eye, and hand, find yourselves able to reliably register in the brain the facts presented to you. The majority of old students are probably thinking of going into general practice, and as one who has been through the mill I venture to address them. I commenced with a pupilage in the country, and although the times are out of joint for a continuance of that system it had many advantages. The first lesson was upon the necessity of professional secrecy. One soon saw the wisdom and utility of the Hippocratic oath and learned to appreciate William Cowper's saying that "confidants in general are like crazy firelocks which are no sooner charged and cocked than the spring gives way and the report immediately follows."

Much is required of the modern practitioner by an exacting public. A confession of ignorance is sometimes necessary, although this requires some pluck and is misunderstood by parents and friends, who expect a medical man to know everything connected with the human body, and that he should be able to work miracles and should not require a holiday. He must be prepared to deal with everything—from advising on the dangers or advantages of cycling to the examination for life insurance. Indeed, one could almost be serious in saying that, of course, the intelligent practitioner will have made himself acquainted with the arguments and experiments of Professor Schenk, for he must now be prepared to stand an examination by the British matron upon the subject of the determination of sex. The authorised English translation (under the supervision of a London physician) is advertised and noticed, I am told, in the ladies' journals and there will be many mothers anxious to try the experiment of securing a son under the guidance of the family medical man. Before entering upon practice it is an advantage to make a voyage or expedition; it gives a wider view of men and things, although some argue that it makes it difficult to settle down afterwards. But, as Hazlitt said, "You will bring with you from your books and solitary reveries a wrong measure of men and things unless you correct it by careful experience and mixed observation"; but this advice should have the emphasis on *careful* experience and should not be taken as an excuse for making observations of too mixed a character. Those students, sons of medical men, going back to practise with their fathers should let them down lightly and not fire off all their lately acquired knowledge to the disparagement of their progenitors. Do all that is possible to secure and maintain a good feeling with fellow-practitioners. Nothing makes matters go easier than a real friendship with others similarly situated.

With respect to a "good bedside manner," if it is natural so much the better, but something may be done to cultivate it without affectation. Lord Chesterfield was of opinion that manner is of more importance than matter, and most of us can possibly recall instances where this seemed to hold good in the practice of medicine. To quote Hazlitt once more, "Gravity is one great ingredient in the conduct of life, and perhaps a certain share of it is hardly to be dispensed with. Few people can afford to be quite unaffected. At any rate, do not put your worst qualities foremost." At all events none of you, I am sure, will wish to imitate that personage of whom Tourguéneff said, "He had the air of his own statue erected by national subscription." Those within reach of such advantages will no doubt avail themselves of the excellent arrangements now made for "post-graduate" instruction, and they have also the advantage of getting the aid of the consultant in serious cases. This relief in responsibility is more often denied to the remote country practitioner, who should, I think, be considered himself as a specialist of specialists, and be an exceptionally strong man.

In these days of anæsthetics, provincial practitioners should be prepared to administer them with the confidence begotten of practical experience, and certainly they will do well to make themselves as expert in the use of nitrous oxide as is the dentist. The latter sometimes complains that at present he has really to administer the gas whilst the family medical adviser can merely sit on the window-sill and look on. To all I would recommend an early attendance upon midwifery cases. When once summoned you will not feel comfortable until a visit has been paid and when once it is recognised that such is your rule and that it is unnecessary to give a long warning to ensure attendance it will be found that false alarms will not occur so often and any leisure time thus gained can be legitimately enjoyed. Another point of importance is to have a good knowledge of children's diseases, a matter too often neglected. It is not too much to say that the young practitioner who can show that he is a capable obstetrician and understands the treatment

Digitized by Google

and right feeding of children has the best of introductions to general practice, and it will be his own fault if he does not become the trusted family attendant on all occasions when one is required.

Do you ask me what is the reward for your efforts? I think not; neither is it necessary to speak of punishment for failure. No hope of "making a fortune" has led your footsteps into Medicine. An honourable competence in return for a conscientious and self-denying life well spent in the service of your fellow-creatures is what you aspire to, and no eloquent quotation as a peroration to my remarks can add to your zeal. But in the name of the Medical Faculty of University College I can assure you all of their best wishes for your success.

ROYAL FREE HOSPITAL: SCHOOL OF MEDICINE FOR WOMEN.

INTRODUCTORY ADDRESS BY DR. J. WALTER CARR, ASSISTANT PHYSICIAN TO THE HOSPITAL, ON "FASHION IN MEDICINE."

I CAN well imagine that many now present who are new, and some perhaps who are not new, to the study of medicine will start at the mention of the word "fashion," and especially at the suggestion that in medical questions we are subject to its rule. But those who take this view forget that we are human beings first and medical men or women afterwards, and that loftily though we may talk of medical science yet we necessarily bring with us to its study all our natural weaknesses, prejudices, and superstitions; also that it comes to but few to make new departures, to take a fresh initiative, or to get out of some old rut of thought or practice. The great majority must necessarily be followers, not leaders, and hence it comes to pass that in medicine, quite as much as in any other sphere of life, we are subject—often helplessly and hopelessly—to the bondage of fashion, custom, habit, and authority. It is as requisite to be orthodox in medicine as in theology; in fact, I am not sure that lawlessness in the medical world does not bring down more severe punishment, and certainly gets less appreciative sympathy, than lawlessness in the Church.

It is an interesting and instructive, albeit somewhat humiliating, study, even if we confine ourselves to comparatively recent times, to follow the influence and vagaries of fashion in pathological theories and dogmas and still more in the domain of treatment. Let us deal merely with a few of the chief methods which have been popular in the treatment of fever and inflammation as exemplified, say, in such well-marked and relatively common diseases as pneumonia, typhoid fever, and rheumatic fever.

Little more than fifty years ago a fever was regarded as a sort of morbid entity to be expelled from the body by thoroughly drastic measures. The sheet-anchor of the treatment was venesection, but this was assisted by the free use of depressant and nauseating drugs such as antimony, by mercury pushed to the limits of tolerance or beyond, by purgation and by blistering, and by semi-starvation as a further inducement to the fever to depart. With present-day notions and experience these things may sound almost incredible, but read the directions laid down by eminent authorities for the treatment of pneumonia: "You bleed early from the arm and if necessary you bleed a second or a third time, and if under this treatment resolution does not speedily take place you bleed locally by leeches or by cupping and likewise give tartar-emetic more or less freely, to all of which counter-irritation may be superadded in the more advanced stages. Mercury is also to be given freely, even to salivation, combined with opium." Sir Thomas Watson, the leading physician of his day, lecturing a little over half a century ago, at a time when bleeding was becoming rather less popular, recommends blistering for pneumonia, but says it should not be done in a half-hearted fashion: "The patient should have a waistcoat almost, or at any rate a breastplate of blistering plaster." Speaking of the treatment of pleurisy he says: "Cover the side with leeches and when they have sucked forth what they can let their bites continue to discharge blood into a thick, absorbing poultice." Patients suffering from acute rheumatism seem to have undergone even more heroic treatment, probably because it naturally runs a more protracted course than does pneumonia. We have the notes of the case of a man, aged twenty-eight years, treated in King's College Hospital in 1840 for two attacks of rheumatic fever; for the first attack he was in the hospital six weeks and for the second fourteen weeks, with an interval of only about a month between. I will not weary you with the details of the numerous bleedings, cuppings, leechings, and blisterings to which he was subjected; suffice it to say that in all 110 oz. of blood were withdrawn besides that which was lost by leeches, and that the latter was no inconsiderable amount may be inferred from his having as many as ten leeches applied at once to an inflamed joint. The additional fact that at one time he was also given 3 gr. of calomel every 3 hours is to be regarded as a mere detail of treatment scarcely worthy of note. The result hardly seems to have been satisfactory, for 2 months later he was readmitted, but the notekeeper appears to have got tired, for though the patient is said to have ultimately recovered the date of his discharge is not recorded. A few years later the treatment had become less heroic, but a vigorous administration of calomel was believed in by some. In Sir Thomas Watson's lectures we read: "Some have given large doses of calomel in the outset of the disease, such as half a scruple or a scruple, repeating the dose daily or oftener with occasional purgatives perhaps till the urgent symptoms gave way, and in this manner I have seen the disease apparently cut short. But I have also known many instances in which the disease was painful and protracted and obstinate, although this practice was adopted early and fairly prosecuted." Yet in these degenerate days I have already well-nigh grown tired of encouraging cautious house physicians to give a single small dose of calomel at the commencement of the treatment of a case of rheumatic fever. It would be easy to multiply examples of this kind of thing; I will add but one more. "A child of twenty-eight months took in nine days 350 grains of calomel and in six of these days 136 grains of jalap"; she was suffering from cerebral symptoms, upon the cause of which it is useless to speculate. The point is that the child recovered; under modern treatment she might not have done.

What was the meaning of all this energy? Our medical predecessors were by no means fools and we must not imagine that all their treatment was useless or barbarous. One reason for the continuance of this heroic treatment was doubtless the fact that in a certain number of cases it was successful, sometimes eminently and strikingly so. Now from these instances of success two fallacious arguments arose: one is the idea that because a little blood-letting sometimes did good that more would do more good, or that if one venesection failed to give relief repeated withdrawals of blood might attain the desired end; the other, that because venesection was beneficial in some cases of fever or inflammation that therefore it would probably do good in all, forgetful that other circumstances might be entirely different. No one of course would dream now of bleeding a typhoid fever patient, yet in one of the worst cases I have ever met with a moderate intestinal hæmorrhage was followed by marked improvement in the mental state, the patient regaining consciousness for the first time for over a week. On another occasion an attack which gave every indication of being a very severe one became exceedingly mild after a profuse epistaxis. Of course, the improvement in each case may have been a coincidence merely, none the less it was very marked, and it is easy to imagine the medical men of a former generation pointing to such cases as conclusive evidence of the value of blood-letting.

As was inevitable, a tremendous reaction set in against the lowering treatment of fevers; Dr. Graves in Dublin taught that fever patients should be fed and not starved and desired that the epitaph on his tombstone should be, "He fed fevers." But the reaction went further and an actively stimulant treatment became the fashion. Dr. Todd of King's College Hospital, one of the leaders of the reactionary movement, thus describes his treatment in 1851 of a severe case of typhoid fever in a strongly built man, aged thirty-two years. From Jan. 21st to the 27th the patient took half an ounce of brandy every hour. "I now," says Dr. Todd, "doubled the quantity of brandy and ordered ammonia and chloric ether every fourth hour. On the 29th I felt it needful to increase the stimulant to 5 drachms every half hour, or 30 oz. in the day. On Feb. 3rd the stimulant was reduced by 6 oz., so that he now took 1 oz. every hour instead of 10 drachms; the chloric ether was omitted." After this the patient slowly sank and eventually died from intestinal hæmorrhage on Feb. 9th. "Under the highest stimulation all the symptoms improved, the chest became more free, the head clearer, the fever

Digitized by Google

less, the tongue cleaner." Says Dr. Todd, almost pathetically: "I do not see what more we could have done; we cannot plead guilty to the charge of *nimia medici diligentia*." Again, a girl of fourteen years was given 1½ oz. of brandy every hour for three days together, and for the next fortnight ½ oz. was administered hourly, this being sometimes much increased as occasion required; she recovered. An eminent physician, not dead many years, used to teach: "There is one drug for pneumonia, it is in your Pharmacopœia—brandy, give it." It is true that not all cases were treated in this heroic fashion; still, as the idea grew that alcohol was *the* drug for fever, so the fashion spread, until it was given more and more freely, more and more indiscriminately.

Again, and naturally, came the reaction, and just as vegetarianism is to be looked upon as the practical protest against our excessive meat-eating habits, so the outward and visible sign of the reaction against unreasonable alcoholic stimulation is the temperance hospital. And yet surely so extreme a protest is as unscientific as the practice protested against. Disease may undoubtedly be treated, and successfully treated, without venesection and yet a timely resort to bleeding may certainly be of the utmost value. Why abandon the practice altogether because it has been abused? So no doubt we can to a considerable extent substitute other things for alcohol, and yet why deliberately deprive ourselves of even a single remedy which may at times at any rate be of the greatest utility?

The next fashion in the treatment of fever was the endeavour to reduce the temperature, mainly in two ways—either by the direct application of cold or by the administration of drugs. With regard to the cold treatment little need be said: its tendency on the whole has been beneficial, and though, like everything else, it may be carried too far, yet excess and undue enthusiasm are largely cooled by the practical difficulties in the carrying out of the treatment and by the natural prejudices of the patient or his friends, more especially against cold bathing. Still we need to beware of the old fallacy that because cold baths may undoubtedly save life in hyperpyrexia therefore external cold is necessarily equally useful in milder cases of fever. There is really but little in common between the two conditions. A very different matter is the artificial reduction of temperature by powerful drugs—antipyrin, antifebrin, phenacetin, &c. When first the antipyretic action of these bodies was discovered men thought that fever was for ever robbed of its terrors—that once keep down the temperature all other bad symptoms would disappear. The result was that any rise of temperature was merely regarded as nature's invitation for a knock-down blow from a well-chosen and well-administered antipyretic drug. As a consequence the therapeutical art never perhaps in this century reached a lower level. If a patient had fever, no matter from what cause, very little matter of what degree, the practitioner's one idea was to reduce his temperature. Is it any wonder that when the influenza epidemic appeared, with its great and sudden rises of temperature, the public should think that they had the key to its successful treatment in their own hands and that sufficiently large doses of antipyrin would soon cure them? Can they be blamed for endeavouring merely to improve upon the teaching of their professional advisers? However, the discovery was soon made that even though it was possible to reduce the temperature it was not equally possible to relieve the attendant symptoms; that although we might cut short a pyrexia we could not cut short the disease of which the pyrexia was merely one of the symptoms; and, further, that whilst we were attempting exclusively to relieve the one symptom, the high temperature, other symptoms might get worse and even new ones might develop. We began even to learn the lesson that nature has always been trying to teach us in some of the worst and most fatal varieties of peritonitis and pneumonia, the apyrexial forms, that moderate fever is a friend rather than an enemy, that its absence is often one of the most serious of symptoms, and that its presence is to be regarded as nature's defensive reaction and method of bringing the disease to a natural and fortunate termination; and although like so many reactions even that of fever may be excessive and fraught with its own dangers, yet our safest plan is not hastily to interfere with the indications furnished by that safest of all guides—nature herself.

Leaving for a time the various methods of treating fever, it would be an easy task, and one which might conduce to a little needful humility in matters medical, to refer to some of the various ways in which from time to time fashion has swayed pathology, diagnosis, and treatment—the manner in which it has influenced the drugs we have administered, the dietary we have advised, the quantity and form of alcoholic stimulant we have sanctioned, and the special climate, watering-place, or health resort we have recommended. What an opening is afforded for the medical cynic by the way in which newly discovered drugs are boomed, recommended as remedies in every possible disease, and lauded as sovereign cures for a dozen diverse conditions, utterly forgetful of the fact that most medicines are successful when the patient is tending to recover or is merely suffering from some temporary functional disturbance. Finally, in a longer or shorter time most of these much vaunted drugs are consigned to oblivion until possibly their virtues are rediscovered by some future investigator. A whole address might easily be devoted to a record of the different pathological views held as to tubercle and phthisis and an account of the various remedies advocated for their cure, from the specific of some obscure empiric whom we contemptuously designate a quack up to the scientific remedy elaborated by some leading pathologist whose discovery, under most august and imperial patronage, sets the whole civilised world in a flutter of excitement until it, too, is relegated to the limbo of useless discoveries. Of course, in these up-to-date times it is beneath us to read old books. We are content to pay large prices for them as curiosities for our libraries, just as we do for the skeleton of a dodo to preserve in a local museum; otherwise Jonathan Swift's account of the philosophers and projectors in the Academy of Laputa might even now be found interesting and not unprofitable reading.

Just at present there are two especially fashionable tendencies in medical treatment. The first is the use of antitoxins and animal extracts; those of us who are not unnecessarily sceptical may, in fact, look forward to the medicine of the future being enormously simplified, somewhat on the following lines. Most diseases will be grouped under two heads, those in which some organ or tissue is diseased so that its internal or external secretion is suppressed or altered and those due to a micro-organism or the toxin produced by it. In the first case the treatment will, of course, be the administration of the suitable animal extract; the remedy is ready to hand, for already, according to a recently published work, we can select from extracts of bone marrow, lymphatic glands, heart muscle, brain, spinal cord, kidney, liver, pancreas, parotid, pituitary body, spleen, suprarenals, thymus, thyroid, and even other less likely organs. Such is the vast superstructure which has been built up on the success of the thyroid treatment; again the old fallacy that because one animal extract has done good others will be equally useful. If, on the other hand, the body be invaded by a pathogenic micro-organism it will only be necessary to inject the requisite antitoxin—that of cholera, diphtheria, glanders, plague, rabies, septicæmia, tetanus, tubercle, pneumonia, typhoid, &c., &c., as the case may be. How delightfully simple will therapeutics be in the future.

[Dr. Carr here argued at considerable length that the highest function of medical practitioners is not to attempt to cure diseases by means of specifics but to be apostles and preachers of hygiene. He continued:—]

Any consideration of the recent developments and tendencies of medicine would obviously be incomplete without some reference to the extraordinary growth within the last generation of the nursing system, to which all medical men owe so much. For the present nursing and nurses of our great hospitals and of an increasing number of our large infirmaries there is little but good to be said; of course they are not perfect, because no individuals are perfect, and doubtless there are slight differences in the standard of efficiency in various institutions. Necessarily also the presence of medical students in a hospital introduces fresh difficulties and complications. We now recognise the trained nurse as an important factor not only in hospital but also in social and domestic life. There has been during the last few years an enormously increased demand for and a proportionately increased supply of, nurses in private work, and it is in this direction, I think, that a danger exists of the movement being carried too far, and with any such excess comes necessarily in the future the even greater danger of a disastrous reaction. As nurses increase so enormously in number there is almost inevitably a falling off in quality. Some nurses again, and not a few in private employment, are in danger of thinking of themselves more highly than they

Digitized by Google

ought to think; as has been well said, they have a profound contempt for the general practitioner, barely tolerate the physician, and have a real respect only for the operating surgeon, provided always that he uses the particular dressing to which they have been accustomed. What their feelings would be towards a female practitioner I cannot find adequate words to express. Perhaps the most serious danger of all is a growing tendency towards allowing the nursing of the sick in the houses of the middle classss of our country to pass entirely into the hands of strangers, so that domestic nursing is likely to become a thing of the past. I do not speak of the upper classes, for the smart ladies who try to escape the cares and troubles of maternity are not likely to seek the responsibilities of nursing either their husbands or their children and amongst such trained nurses are a necessity, but with the middle classes it is different and one great feature of woman's influence in the home will be lost if she wholly abandons to strangers the nursing of those near and dear to her and especially the nursing of her children when ill.

My surroundings to-night urge me to inquire into the position and future of one of the latest, and to many here the most important, of all recent medical fashions—the movement which has led to the medical education of women and which brings us together now. Is this to be only a passing fashion, like others to which reference has been made to-night, or is it a true and natural evolution, destined to grow to greater proportions and to take a permanent place in the future history and progress of medicine? I can imagine that many will think it very superfluous to ask such a question at a moment when the cause, having successfully weathered the storms and perils of its earlier years, seems now to be passing into the sunshine of prosperity: when royalty smiles upon and gives its patronage to the movement; when the number of students is steadily increasing; when a new medical school is rapidly rising to bring to the highest attainable standard of excellence our professional education; when public bodies all over the kingdom are throwing open appointments to our graduates; when the Indian Government, the Post Office, the Metropolitan Asylums Board, the London County Council, and boards of guardians in all parts of the country alike welcome the services of the medical woman; and when the opponents of the movement maintain from their last stronghold in that most exclusive, conservative, and aristocratic of medical bodies, the Royal College of Physicians of London, a hopeless and almost pathetic resistance, well knowing that the fates are against them and that though they may retard they cannot much longer hold out against the flowing tide of public and professional sentiment. Nevertheless, our cause is even yet not so firmly established that we can afford to be in the slightest degree negligent or careless. In the early days when openings were few and obstacles many the quality of our students was, I think, proportionately high; difficulties attracted and developed—as difficulties always will—a strong and indomitable race; but when good fortune and popular favour await us—when our movement, in short, becomes fashionable—then comes the danger that though the number of our students may increase there may be a falling off in quality. When women begin to come here not for genuine love of medicine, not with earnest purpose of work, not with a fixed determination to overcome all obstacles and surmount all difficulties, but because it is fashionable to come, because it is a recognised mode of passing time which hangs too heavily, of obtaining a larger measure of freedom, or of escaping from a home which for some reason or other has become uncongenial; if the work is pursued in a merely dilettante spirit, if students enter and, worse still, become qualified, whom nature never intended for medical pursuits, then indeed our position will be in jeopardy and a reaction might speedily arise which, if it did not submerge the cause, might easily set it back many a year. In a more than ordinary degree, therefore, a great responsibility rests upon each individual student here, as indeed must always be the case with the pioneers and early adherents of any comparatively new movement, no matter what its character, be it religious, educational, philanthropic, political, or social. Collectively you are somewhat in the position of a young practitioner just established behind a brass plate who is called upon in an emergency to attend a new patient as compared with the old-established family medical attendant. In the latter all kinds of eccentricities and even trivial errors will be overlooked or condoned—if he has once gained the family confidence and respect he will not easily forfeit it; whereas in the young practitioner the slightest indiscretion, the most venial mistake, may be sufficient to ruin his reputation and wreck his career, however promising. As it is with the youthful practitioner individually so it is with the cause of medical women as a whole. Amongst male practitioners the public recognise that there are sure to be some failures, some doubtful characters, some foolish or ignorant persons, some disreputable individuals, and the existence of a few such does not materially injure the reputation or position of the profession as a whole; but, for the present at any rate, whilst the women's movement is still young, were there to be any serious falling off in the character and quality of the students, were we to send out into the world practitioners ill-qualified or unsuited for their work, were any medical women to be guilty of serious moral or professional indiscretion or to show themselves unworthy of the responsibility thrown upon them, then we may be assured that a thoughtless and indiscriminating public would at once jump to the conclusion that female practitioners were a failure. Once again, therefore, I would most earnestly impress the immense responsibility which rests upon each one here, first of all during student life and still more when, duly qualified, you have to act on your own resources, being assured that any untimely frivolity, any want of tact or discretion, any carelessness or dereliction of duty, will not only injure your own professional career but may seriously damage the entire cause of the medical education of women; for instance, anyone who is a failure in a resident post in a hospital, infirmary, or asylum will almost certainly ensure that post not being again given to a woman and will probably prevent other similar openings being provided in the near future.

In one respect at least medicine must ever be the most trying of vocations, because to us is entrusted that greatest of all responsibilities, the responsibility for human life, and we need ever to keep before us the fact that whilst in so many of our cases life hangs in the balance and the smallest factor may turn the scale this way or that, yet the flickering spark which the least mistake may so easily extinguish, no skill, no effort, no devotion, no regret of ours can ever restore. I urge you, then, to use every advantage and every opportunity of acquiring knowledge during your hospital career, so that in after-life you may never have the painful recollection of neglected opportunities in student days.

ST. THOMAS'S HOSPITAL.

AT this hospital no address was given by a member of the medical staff, but on Oct. 3rd, in the presence of a large audience, the Bishop of Rochester, presented the prizes won during the recent examinations at the school. Mr. WAINWRIGHT, the treasurer, who presided, said that we lived in times when we could not stand still, and no one, he thought, could say that that institution had stood still, for during the last twenty years the hospital had been the centre of great activity. They had only recently established a clinical laboratory, which was unique of its kind in London, and would be of the greatest utility in assisting students to carry on their work. They had during the year reopened another ward which would provide increased accommodation for 150 patients a year, while they were opening another ward which was to be christened the City of London Ward. He wished it to be known that that was a City hospital and hoped that the example set by the Mercers' Company in giving them £10,000 would be followed by other City bodies.—The prizes having been distributed the secretary, Mr. G. RENDLE, pointed out that during recent years large sums of money had been spent on the schools, and consequently it was not anticipated that any further considerable expenditure would have to be incurred for some time to come.—The Bishop of ROCHESTER in his address said he had always felt the close affinity between the medical and clerical professions. Both were constantly acquainted with the more squalid and less attractive side of human life and both could not protect themselves, as members of some professions could, by rules, but they had to be always ready at every call, and family comfort, rest, and even health, had often to be sacrificed to the call of duty. Beyond that also he found the work of the two professions similar, as they both aimed at wholesome life.

THE Pharmaceutical Society of Great Britain is closely allied in its work with one side of the work of the medical schools, and we have pleasure in publishing an abstract of Sir James Crichton Browne's address to students delivered

Digitized by Google

before the society at the opening of the winter session. We also give a brief *résumé* of Mr. Walter Long's remarks at the Royal Veterinary College.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

INTRODUCTORY ADDRESS BY SIR JAMES CRICHTON BROWNE, M.D. EDIN., LL.D. ST. AND., F.R.S., ON "POISONS AND POISON LEGISLATION."

GENTLEMEN,—It is my privilege this afternoon to address to you a few words of exhortation and encouragement on the occasion of your entering on a course of study which is the appointed avenue to that manor of usefulness in which you propose to dwell and earn your subsistence. I cannot in doing this hope to speak to you with the insight and exactitude of one who has actually followed the calling which you have chosen, but I can, at any rate, bring to the performance of the duty I have undertaken a sympathetic interest in your life work and a knowledge of its needs, trials, and opportunities second only to that of those who have personally borne the burden of them. For the view which a medical man takes of the business of the pharmacist is not altogether exoteric. He has been behind the scenes if not the counter; the mysteries of the mortar are well known to him; the language of drugs is ever on his lips, their actions and reactions daily occupy his thoughts, and the responsibility attaching to their use weighs upon him incessantly. It is indeed sometimes difficult to say where the medical man ends and the chemist and druggist begins, and while, for my own part, I trust that the line of demarcation between them will become more and more sharply defined as time goes on, so that we shall have fewer prescribing chemists on the one hand and fewer dispensing medical men on the other, there must always remain a close alliance between your calling and mine. They have common aims, they use the same weapons, they are complementary to each other, and it is to be hoped that they will be always animated by mutual good feeling.

[Sir James Crichton Browne here referred to the raising of the standard of education for dispensing chemists which had been brought about of late years. He continued:—]

But while we rejoice at the rectification and sublimation of chemists and druggists that is going on we must see that this process is not carried too far or unduly accelerated. In this, as in so many other matters, it may be well to hasten slowly, for, remembering the very special circumstances under which the studies of embryo chemists and druggists are carried on, there would seem to be a special danger in submitting them to sudden or severe mental strain. They are earning their bread all the time; they are able to give to their studies but brief periods carved out of toilsome days; they bring to them brains, not fresh and nimble, but fatigued and sluggish; they pursue them, not with entire devotion, but harassed by the petty troubles of the shop, and they are liable, therefore, to be injuriously affected by a degree of mental pressure which would be harmless and even stimulating to young men who have nothing but their studies and their pleasures to attend to and whose daily life is ordered with a single eye to their schooling. We are suffering largely in this country to-day from stupidity which has been manufactured by examinations, and I do not doubt that a point may be reached in the examination of chemists and druggists which will conduce rather to dulness than alacrity of thought, which will sacrifice to temporary mental engorgement, with a subsequent life-long disgust at learning in any form more concentrated than the newspaper, the well-regulated and wholesome nutrition of all the faculties and an enduring appetite for knowledge, and which will at the same time stunt bodily growth and sow the seeds of ill-health. I do not for one moment suppose that the examinations to which you are exposed have reached that point or are approaching it. As far as I am able to judge they are moderate and reasonable. I only wish to indicate certain risks which lie ahead—risks which will, I trust, as they arise, be obviated by the wisdom and caution of the Council of the Pharmaceutical Society.

[Sir James Crichton Browne then discussed the examinations in question. The first, he said, was quite a reasonable one; the second, the "minor," examination, might, he suggested, be divided into two parts, and he earnestly entreated all masters to see that their apprentices had plenty of time not only for study but also for that leisure without a sufficient supply of which good work is impossible. As to the "major" examination, although it was not necessary that it should be taken yet he hoped that more and more persons would continue to avail themselves of it. After referring in laudatory terms to the work done by the Pharmaceutical Society in bringing out the new British Pharmacopœia Sir James Crichton Browne continued:—]

Another notable event of this year in your department besides the appearance of the new Pharmacopœia has been the addition to the statute-book of a Pharmacy Amendment Act, which, owing to the determined exertions of your President, Mr. Walter Hills, has survived the slaughter of the innocents. It is a modest measure providing for the election of apprentices or students as Student Associates, and for registered chemists and druggists as Members of the society, and for the retirement by rotation of members of the council, and I have no doubt it meets felt requirements. Unlike all previous pharmacy enactments it has nothing to say about poisons, which have invariably been the real motive power in legislative measures affecting your trade. It is not so much as pharmacists as vendors of poisons that you have secured the attention of Parliament, and as that branch of your avocation is the most anxious and hazardous of any, has a peculiar interest for the public, and is very likely to be made the subject of a Bill next session at Westminster, it occurs to me that I may not inappropriately make poisons and poisoning the theme of some remarks to you this afternoon.

What, it may be asked, is understood by the term "poison"? And the first answer to that question which presents itself is any substance that, when introduced into the body, produces injurious or fatal effects. But for practical purposes that definition is much too comprehensive, for certain articles of food and drink, when taken too freely or in disordered states of the system, or by persons of peculiar idiosyncracies, may prove detrimental and even kill, while almost all the drugs in common use, if given in excessive doses, may cause symptoms of poisoning and death. The question of quantity enters into our conception of a poison which may be described as a substance which in small amount and by chemical action has hurtful or lethal effects on the animal economy. This description cannot pretend to strict accuracy, for some poisons perhaps act mechanically, as, for instance, certain microbes which block up the blood-vessels, and ground glass, which in some parts of the world has not infrequently been used as a slow irritant poison. But the vast majority of poisons destroy the living tissues by means of chemical action. Even thus restricted, however, the word "poison" covers a multitude of agents, for on every shelf in your shops stand chemical assassins capable in small bulk of undermining health or taking life. Indeed, so numerous are the drugs which must be scientifically regarded as poisons that it has been said that to select and schedule a few of them which may not be sold without reservations while the rest are left unguarded is like prohibiting the carrying of knives while allowing stilettos. But although, as you and I know very well, there remain outside Schedule A many drugs as mortal as any included in it, and more difficult of detection, and although with the advance of science the field from which the poisoner may cull his simples is ever widening and becoming more variegated in its crop, it must still be maintained that Schedule A has done great public service. It may be logically indefensible, but it is practically useful. During the present year we have had an illustration in the St. Neot's case of the way in which a faithful observance of the regulations connected with it may bring a criminal to justice, for it is quite likely, I think, that Horsford would have escaped conviction had Mr. Payne failed in keeping an accurate record of the sale of the strychnine to him. As a matter of fact, the poisons enumerated in Schedule A are those which have been, and are almost invariably, employed for felonious purposes.

In looking over the history of poisoning—I am speaking now of homicidal poisoning—nothing strikes me more than the way in which this kind of history repeats itself from generation to generation. The same old implements are used again and again and there is an absence of anything like originality or ingenuity in the choice of ways and means. Servile, clumsy imitation is the rule and fashion reigns supreme. Little or no advantage has been taken of the discoveries of science. No doubt we hear about the subtleties and mysteries of slow and secret poisonings in bygone times. We are told that Henry VI. was killed by a pair of poisoned gloves and that victims were in those days simply and expeditiously got rid of by causing them to smell

Digitized by Google

a poisoned rose or to wear or suck a tainted ring like the one that now figures in "The Termagant" at Her Majesty's Theatre, but such stories are on a level with those which we sometimes read in the newspapers of the instantaneous production of insensibility by holding a chloroformed handkerchief to the nose: they are simply incredible. We cannot believe that in pre-scientific days unscientific persons were in possession of powerful agents of which modern science knows nothing, and when we investigate such cases of secret poisoning in these days as we have any record of, we find, as I have said, that there was nothing occult or wonderful in the process and that in nine cases out of ten it was some preparation of arsenic which was employed. It was arsenic which was used by Wonderton in 1384 in his attempt to poison the King of France, Charles VI., and the Dukes of Valois, Berri, Burgundy, and Bourbon. It was arsenic which was the active constituent in La Sarpa's wonderful elixir that played such havoc in Rome in the seventeenth century; it was arsenic which formed the basis of the *acquetta* or manna of St. Nicolas of Bari and of Toffania of Naples, which caused the death of 600 persons; and it was arsenic which was the leading ingredient in the succession powders of Sainte Croix, which were used by the Marquise de Brinvilliers, and with which she removed her father, two brothers, a sister, and several other persons. It was arsenic which was no doubt mainly instrumental in carrying off Sir Thomas Overbury in the Tower, although in his case it was combined with cantharides, lunar caustic, and spiders—the *coup de grâce* being given by corrosive sublimate. Wherever we turn in mediæval toxicology or that of the Renaissance it is arsenic, arsenic, arsenic, which was the mainstay, not merely of the murderous fortune-telling hag, but of homicides of commanding intellect and power, like the Borgias and Catherine de Medici. Of course, in those days, and well up to the early part of the present century, it was impossible to distinguish arsenic with any certainty in the bodies of persons who had died from it, while only the vaguest notions prevailed as to the pathological effects caused by it in the viscera, so that it could be used as a poison with considerable impunity. But since Orfila, Reinsch, Marsh, and others have carried out their researches it has become of all poisons the most easily recognised by chemical tests, while its symptoms and morbid anatomy are familiarly known to the medical profession. And yet, notwithstanding this, it is still, no doubt owing to the facility with which it may be procured and its old-established reputation, a favourite with the homicide. Mrs. Cotton, who was executed at Durham in 1873, was arraigned on four separate charges of poisoning by arsenic. Mrs. Maybrick was convicted of having administered it to her husband in 1886. Mrs. Sherman, of New Haven, United States, was proved at her trial in 1885 to have disposed of three husbands and some seven or eight children and step-children by means of it, while in the same year Mrs. Robinson, of Somerville, Massachusetts, was shown to have been indebted to it for the disappearance of six members of her immediate family. I am sorry to have to say so, but it is true that women and medical men are the classes which have supplied the most numerous and most notorious poisoners. Man—in this connexion *minus* medical men—bold and militant, is disposed to crimes of violence; woman, weak and timid, when she stoops to crime inclines to craft and cunning, and hence she has often sought, by the arrow that flieth in darkness, to remove a rival, to resent infidelity, to avenge her wrongs, to hide her shame, or to gratify her cupidity. At certain periods poisoning by women has been epidemic and has anticipated the decrees of our modern divorce court. About the middle of the seventeenth century it was observed that young widows were extraordinarily abundant in Rome, and that most of the unhappy marriages were speedily dissolved by the illness and death of the husband; and inquiries set on foot by the clergy, who felt bound to make representations to Pope Alexander VII., resulted in the discovery of a secret society of young matrons, who met at the house of a reputed sorceress for technical instruction in toxicology and mutual improvement in marital euthanasia. A little later a similar organisation was brought to light in Paris, again by the action of the clergy, and here it was shown that under the guidance of two nominal midwives, La Voisin and La Vigoroux, large numbers of married women had hastened the decease of their husbands. It was not until upwards of a hundred culprits of this description had died at the stake or on the gallows that this epidemic was stamped out. In Hungary, in the latter half of the seventeenth century, and again only a few years ago, extraordinary disclosures were made as to wholesale husband poisoning by women of the peasant class who, like the Roman and Parisian matrons, employed arsenic to compass their ends.

We can understand in some measure the partiality of female poisoners acting individually and in numbers for arsenic, and their rigorous adherence to ancient methods by remembering that arsenic has long been employed in many countries as the most popular domestic exterminator of vermin and has also been extensively recognised as an article of toilette, so that women have been able to obtain it and explain their possession of it on these pretexts; but it is difficult to comprehend why poisoners of the other group alluded to, medical men, should have displayed such poverty of resource as is manifest in their published misdeeds and should have confined themselves so strictly to the contents of Schedule A. One would have thought that medical men, with their knowledge of drugs and command over them, would have been able to ring the changes in an infinite variety of ways and to employ alkaloidal and other organic poisons in such a manner and in such combinations as to perplex the clinical observer, baffle the pathologists, and set at nought the skill of the analyst. But not so. With what might almost be called infatuation they have all but invariably worked on in the old grooves and carefully prepared a net for their own ensnarement. For the most part they have trusted to the inorganic poisons, which, owing to their unalterable character, ease of purification, and definiteness of reaction, can be identified in the body with mathematical certainty; and when an alkaloid has been essayed it has been strychnia, which, of all the alkaloids, in unalterability and definiteness of reaction, approaches most closely to the inorganic poisons, and to which, too, very conclusive physiological tests can be applied. The rarer and more fugacious alkaloids, which I am not even going to name, and which when detected it would be impossible to affirm might not be putrefactive products—ptomaines, albuminoses, and peptones which result from the decomposition of the tissues or of ingested food—have, as far as we know, never been tried, and even nicotine, the most widely diffused of alkaloids, with which, I suppose, a third of the population is always poisoned more or less has not been resorted to with premeditated malice except in one case—that of Count Bocarne, who poisoned with it in five minutes his wife's brother, Fougnies, although in the body of a murdered smoker it might well pass as a relic of the pipe or cigarette. I cannot recall a case in which a medical poisoner has gone beyond Schedule A. Palmer used strychnine, Smethurst used antimony, Pritchard used antimony, Cross used arsenic, Lamson used aconite; Chantrelle, who, although not a medical man was a chemist, used morphia; and Tawell, who was a chemist and druggist, used hydrocyanic acid. Such are the ignorance, stupidity, and rashness revealed in a review of the trial of these medical poisoners that one is forced to conclude that they were like the miscreants who carry on illicit lines of practice at the present day—medical men only in name, professional pariahs and failures beneath contempt, and that in them, as in the criminal classes generally, intellectual incapacity was associated with moral debasement. Not one instance have we amongst them of average ability, to say nothing of originality or genius, in their nefarious transactions. True, it may be said that the medical poisoners who have been brought to justice have been the clumsy and incompetent members of their class. The bunglers, it may be argued, have been caught, while the adepts have escaped suspicion. It is, I fear, correct that there have been and are cases of undetected poisoning. In almost every instance in which a medical poisoner has been convicted there have been good grounds for believing that he had had other victims besides the one whose death was brought home to him, and several medical men in large practice have told me that in their professional experience they have come upon cases in which they have had grave misgivings that poisoning was being or had been attempted. It may be that medical men have availed themselves of the discoveries of modern science for wicked and unlawful ends and have lived on in the odour of professional sanctity unsuspected; but there is some consolation in the reflection that the more scientific a man is the less likely is he to stoop to any abuse of power that science puts in his hands; and that the improved education of the medical profession renders its members more expert than they have hitherto been in the recognition of the symptoms

Digitized by Google

of poisoning of various kinds. But here I must point out to you that as regards the future of toxicology very serious considerations arise, for numerous new poisons are being yearly added to our list, and many of these it is and must perhaps always be impossible to track and identify. Henceforth the medical man or scientific expert desiring to remove any human stumbling-block in his way, if able to shake off old traditions, will not, unless demented, select his weapon from Schedule A, but from the recently discovered organic poisons that may be used with absolute impunity as regards detection.

[Sir James Crichton Browne here entered on the question of disease toxins and pointed out how the poisoner of the future would in all probability use these agents as the ministers of his vengeance. He continued :—]

You will admit, gentlemen, I think, after what I have said that the science of toxicology is becoming infinitely more complex and intricate than it has ever hitherto been and that very difficult and curious problems are not unlikely to arise in connexion with it in its relation to medical jurisprudence, problems that may puzzle the discernment of even a twentieth-century Sherlock Holmes. "Chemists," exclaimed Count Fosco with an eye to their toxicological attainments—"Chemists—I assert it emphatically—might sway if they pleased the destinies of humanity. ..... On my sacred word of honour it is lucky for society that modern chemists are by incomprehensible good fortune the most harmless of mankind. The mass are worthy fathers of families who keep shops. The few are philosophers, besotted with admiration for the sound of their own lecturing voices, visionaries who waste their lives on fantastic impossibilities, or quacks whose ambition soars no higher than our corns. Thus society escapes and the illimitable power of chemistry remains the slave of the most superficial and the most insignificant ends." But if Count Fosco thus estimated the empire of chemistry and the boundless power which it places in the grasp of its votaries, what would he not have said of bacteriology and of the hidden and thaumaturgic control over their fellow-men which those initiated into its mysteries possess? Into what rhapsodies would he not have risen over these microbic poisons of superlative virulence and subtlety to which we have now attained, the very existence of which may suggest to you that it is superfluous any longer to surround with special safeguards the sale of such comparatively harmless substances as are contained in Schedule A. But in entertaining any such suggestion you would be in error, for whatever the future—the remote future—may bring forth it is certain that for a long time to come a large majority of poisoners will cling to old methods and stake their necks on arsenic, antimony, and strychnine. For one bacteriological Mephistopheles who can possess himself of a microbic poison and use it dexterously there will be at least a dozen despicable wretches who will take what comes to hand most readily in common life and blunder with it egregiously. And beyond all this we must remember that Schedule A is not intended solely for the prevention of murder but is meant to act as a check on suicide and to avert, as far as may be, deaths due to carelessness and accident. Those bent on self-destruction are not likely, unless to cheat an insurance company, to attempt to induce a lingering illness or to seek out an inaccessible and inscrutable toxin, but are certain to prefer "such soon-speeding gear" of yours "as will despatch them straight," and the obstacles which this schedule enables you to put in their way may occasionally frustrate their object or afford them that brief interval for reflection in which the suicidal impulse, when it has reached a crisis, often suddenly dies out. And independently of this schedule, members of your calling are, I believe, not rarely instrumental in preventing miserable beings from shuffling off this mortal coil, for some of them have acquired a quick eye for a would-be suicide and, as in instances which have fallen within my own knowledge, by refusing altogether to supply him with the poison asked for or by substituting for it an innocuous fluid or powder not unlike it in appearance have given him pause and so saved his life. Then, as regards accidental poisoning, which has become more frequent in recent years as the demands of our advancing civilisation have become more complex and various, there can be no doubt that the provisions of the Pharmacy Act, when rigidly observed, tend to limit it, and that they will be still more efficacious in this direction when the recommendation which the Pharmaceutical Society of Great Britain has repeatedly pressed upon the Privy Council to include in the schedule carbolic acid, to which so many deaths are now attributable, has been adopted. A Bill to regulate the sale of certain poisonous substances was introduced into and passed through the House of Lords last session, but failed, I cannot regret to say, to pass the House of Commons, for the Bill seemed to me to be retrogressive in permitting the sale of the substances named in its schedule and of others that the Privy Council might from time to time add thereto, subject to certain regulations, by any person without any licence or evidence of special qualification. The sale of poisons hitherto has been confined to chemists and druggists, who have been trained to caution in dealing with dangerous commodities and who have proved their fitness for such work by passing a stringent examination, and the wise policy would seem to be to entrust to them the sale of other poisonous substances which have come into vogue and in regard to which the public require protection. No regulations, however carefully worded, can make up for the want of knowledge and a sense of personal responsibility, and free trade in poison is not to be desired any more than free trade in alcohol. Labelling alone is not a sufficient safeguard and indeed it may be argued that whenever it becomes very general in its use it will in great measure cease to be protective, for familiarity breeds contempt, and the warning word "Poison" is apt to lose its effect when it is incessantly cropping up. The fact that a particular substance has to be procured at a druggist's shop with certain formalities is, to my thinking, much more likely to create caution in its storage and use than the most flaring superscription of poison if it can be purchased of any ordinary dealer. Of course, one would wish to put no unnecessary obstacle in the way of the distribution of carbolic and cresylic acids, which are so largely used as disinfectants, or of the materials sold for the purpose of destroying insects and vermin, which are now acknowledged to play some part in the dissemination of disease, but it should always be borne in mind that cleanliness is the best of all disinfectants and vermin-destroyers and that sound sanitation should render the use of chemical antiseptics only occasionally necessary. There can, I think, be no hardship in confining the sale of these chemical antiseptics to properly qualified chemists and druggists; indeed, there would seem to be great danger in permitting them to be retailed under any conditions by grocers, by drysalters, by oilmen, or by general dealers, in whose shops they would necessarily be mixed up with various other kinds of goods, in regard to the vending of which no special care is requisite. The habitual caution of the chemist and druggist counts for much—an habitual caution which has become second nature to him and enters into all his doings, even, I fancy, into the sale of a sponge or a bottle of perfume; for anyone who has bought such an article over a chemist's counter must have felt that the transaction was conducted with great circumspection and solemnity and that in making the purchase he was regarded almost as an object of suspicion.

I venture to believe that all the advantages sought by the Bill of last session could be secured by the inclusion of the substances named in its schedule in Schedule A of the Pharmacy Act and I feel strongly that the Council of the Pharmaceutical Society of Great Britain should continue to advise the Privy Council as to the articles to be comprised in that schedule. The Privy Council must have special technical guidance in such a matter and I know not where they could obtain more trustworthy guidance than from the chosen representatives of that body of men who have an intimate practical acquaintance with all the difficulties and dangers attending the sale of poisons and who will not, I am sure, allow their trade interests to stand in the way of the public welfare.

[After mentioning recent researches as to antitoxins Sir James Crichton Browne proceeded as follows :—]

Step by step, armed with our antitoxins and our serums and our lymphs, we are encroaching on the ghoul-haunted regions of disease and bringing hope and healing where before all was darkness and despair. There is no extravagance in the prediction that all the infective diseases will before long be brought under control more or less and have their power of evil vastly restricted if not abolished. And that means more than might at first sight appear, vast although even then is the prospect of benefit to mankind, for diseases hitherto not regarded as infective are being brought into that category or shown to be of toxic causation and therefore amenable to our new methods of treatment. Should it prove, as Nissl and Mr. Lane Hamilton have alleged, that

Digitized by Google

a considerable number of cases of mental disease are due to auto-intoxication, the antitoxins may be instrumental in checking that alarming increase of insanity which is going on amongst us and which statistical ingenuity can no longer explain away. Should Dr. Westura Sambon be correct in maintaining that sunstroke is an infective disease we shall shortly be combating insolation by an antisiriasic serum. If Dr. Buzzard is right in arguing that anterior poliomyelitis is due to a bacterium we shall soon teach that bacterium to circumvent itself and leave little limbs unwithered. It is within the bounds of possibility that by means of an antitoxin we may yet restrain the course of cancer, that "perilous stuff which weighs upon the heart" of the present generation, for we may counteract a poison which it generates and which is perhaps more pernicious than the structural changes associated with it. And this brings me to a consideration in connexion with antitoxins which should not be omitted in any survey of their therapeutic powers, and that is that in some instances, besides saving life, they mitigate the sequelæ which infective diseases so often leave behind them. Given, therefore, to patients who might survive without their aid they still promote speedy and complete recovery by warding off secondary structural alterations in muscle and nerve fibre and in the viscera. We are all aware of the disasters which small-pox leaves in its trail—blindness, deafness, and lameness, although, happily, we see less of these than our forefathers did and than our children may do, unless the faddists be effectually muzzled and effect given to the conscientious objection of the country to the conscientious objector. We know something of the kidney disorders and disorganisation of the middle-ear which so often follow on scarlet fever and of the paralysis which dogs the footsteps of diphtheria, but perhaps we scarcely realise that every infective disease leaves its mark upon the system. I have heard the late Sir William Gull say—and most of his sayings were worth remembering—that it takes a man ten years to recover perfectly from an attack of typhoid fever, and it is certain that the health and happiness and kinetic energy of the community at large will be sensibly augmented by the employment of medicaments which not merely diminish the mortality of a large group of diseases but limit their secondary ravages.

[Sir James Crichton Browne then proceeded to the question of prevention in disease by means of immunisation. Vaccination had done immense damage to the trade of the dispensing chemist, but yet everyone would, as medical men did, hail with delight any falling off in their earnings that corresponded with a prolongation of human life. He continued:—]

When I stood on the brink of this address I proposed to myself, after a few preliminary remarks, to plunge into a subject of some depth but of great allurement and of special interest to you in relation to your present studies. I proposed to speak to you of a great philosopher who was also a practical pharmacist and to show you how Bishop Berkeley's treatise on Tar Water, published in 1744, has a bearing on the medicine and surgery as well as on the speculative thought of to-day. But my preliminary remarks have run away with me. What have, I fear, proved the ill-favoured and lean-fleshed kine of my introduction have eaten up what I flatter myself must have proved the well-favoured and fat-fleshed kine of my main discourse and I find myself beyond bounds both as regards time and your patience without having as much as mentioned Berkeley's name. I must postpone, therefore, to some future opportunity what I have to say about "Siris," its rational empiricism, its optimism, its curious antiseptic anticipations, its learning, its lucidity, and its marvellous chain of philosophical inquiries and reflections, leading up from a humble nostrum to the throne of the Divine Ruler of the universe. Meanwhile I may recommend it to the private reading of such of you as are not afraid of metaphysics, sure that you will find food for thought even in its therapeutical extravagance, and that it will help you in some measure to escape from that dreary materialism to which your avocation perhaps somewhat disposes you. Its pure and lofty idealism, which you may trace flowing on in a continuous and differently reflective stream in the writings of Carlyle and Emerson, may help you, as it has helped many a man, to lay hold of a sustaining faith. Berkeley said, "He who hath not much meditated upon God, the human soul and the *summum bonum*, may possibly make a thriving earthworm, but must indubitably make a sorry patriot and a sorry statesman." It is not, perhaps, within your visions of your lot to be statesmen, but one and all of you should aspire to be good patriots and something more than thriving earthworms and in all your laudable ambitions "Tar Water" will prove a safe stimulant and roborant. Let me thank you for the indulgent audience you have given me and wish you all with all my heart a prosperous and pleasant journey on the road which is opening out before you.

THE ROYAL VETERINARY COLLEGE.

REMARKS BY MR. WALTER LONG, M.P., PRESIDENT OF THE BOARD OF AGRICULTURE, ON TUBERCULOSIS IN CATTLE.

AT the Royal Veterinary College the inaugural address to the students was delivered on Oct. 3rd by Mr. SHAVE, Professor of Anatomy in the College.

Mr. WALTER LONG, who presided over the meeting, in reply to a vote of thanks for taking the chair, said that he believed the veterinary profession could do a great deal to forward the movement of diminishing tuberculosis apart from any step which it might be necessary for the Government to take. All that the Royal Commission recommended that the Government should do was, in the first instance, to provide tuberculin at what would be, comparatively speaking, small cost, and, in the second place, to pay the fee in order to secure properly qualified veterinary surgeons to carry out the operations. The Royal Commission estimated that the cost of the tuberculin would be 3*d*. per dose and that of the individual testing application to cows another 2*s*. 3*d*., making a total of 2*s*. 6*d*. for each case. He did not in any way seek to evade responsibility—that must always rest on the Executive Government in matters of this kind—but he now said what he had stated elsewhere that if he could only be satisfied that there was a general desire to make use of this particular remedy there would certainly be no unwillingness on his part to obtain the necessary consent of the Government to grant the fee. He would, however, like to impress on them that if a remedy of this kind was as effective as science alleged, surely it could hardly be necessary for the Government to pay the 2*s*. 6*d*. per cow in order to induce the owners of horned stock to take advantage of it. The real truth of the matter was that the men who had the scientific knowledge did not make sufficient use of the opportunities presented to them to infuse their own beliefs and confidence into the minds of the general public. This was one of the most important discoveries which had ever been made, because if it were carried out with the success which was foretold, not only would it eradicate the disease which was causing great loss to the owners of stock, but scientists told us that simultaneously would come the eradication of consumption among human beings, which had brought sorrow to so many homes and which had for so long been regarded as an incurable disease.

THE PREVENTION OF TUBERCULOSIS.[1]

BY CHARLES EGERTON FITZ-GERALD, M.D. ST. AND.,
PRESIDENT OF THE FOLKESTONE MEDICAL SOCIETY.

THE time is, it is to be hoped, fast approaching when the medical profession will assume its proper position as guide, philosopher, and friend, not only to the individual, but to the community at large. There are already indications in America, Germany, and elsewhere that public opinion is trending in the direction of not only allowing medical men to offer advice as to the prevention apart from the cure of disease, but also to enforce its acceptance. Already something has been attempted in this direction by the passing of the Contagious Diseases Act, the Vaccination Act, and the Infectious Diseases Compulsory Notification Act. The first two have unfortunately been stultified and nullified in obedience to the mischievous outcry of a minority of well-meaning but ignorant and sentimental faddists. The Compulsory Notification Act requires to be more comprehensive, and especially should it be rigidly enforced in all cases of tuberculosis. Why should not we in England

[1] A paper read before the Folkestone Medical Society.

Digitized by Google

follow the noble example so admirably and successfully inaugurated in New York by Dr. Hermann Biggs, Dr. Loomis, and Dr. Mitchell Prudden in combating this fell disease? The greater number of the following observations are founded on the reports of this excellent work which have been placed at my disposal by Dr. Hermann Biggs. Of course, there would be at first the usual outcry about interfering with the liberty of the subject, but such protests are comparatively harmless, as has already been proved in America, where there is little or no opposition to the rigorous enforcement of the law by the New York Board of Health. The liberty of the subject has to be curtailed in the case of individuals who are imperilling the safety or lives of the community; why, then, should there not be restrictions on those who, by their carelessness, ignorance, or wilfulness, entail sickness, suffering, and death on millions of their innocent fellow-creatures, aye, and on millions yet unborn? Syphilis and tuberculosis are the greatest scourges of humanity—the former sapping the vigour of the flower of the land, stunting our youths, degrading our women, contaminating our children, and ruining the army on which our empire depends. But it is specially to the notification and prevention of tuberculosis that I wish to call attention—tuberculosis, which causes from 15 to 30 per cent., and in some exceptional cases from 50 to 60 per cent., of all deaths between the ages of fifteen and fifty years. I would ask if it be not time for us, as a profession, to unite at least for the good of others, if not for ourselves, and proclaim to the public with no uncertain voice that they must and shall take heed to the voice of sanitary science and take measures to prevent under rigorous penalties the reckless dissemination of tuberculosis? This they will the more readily do when they are taught to understand that it is an ever-present danger to which each and all are exposed, and this truth should be unceasingly impressed on both the classes and the masses, who should be educated by our profession by mouth and broadcast pamphlets. Ransome, in the Milroy Lectures, estimates that 70,000 persons perish annually from tuberculous disease in this country alone and that in the form of phthisis it is the cause of death between the ages of fifteen and forty-five years (the most useful stage of human existence) of more than one-third, and between the ages of fifteen and thirty-five years of nearly one-half of all who die annually. The monetary loss to the country by this mainly preventable sickness and death must be something enormous. Dr. J. M. Lindsay, in an excellent paper on the Problem of the Consumptive Poor, estimates from reliable data that the persons suffering from phthisis at the present time in the British Isles cannot be less than a quarter of a million. He also laments the lack of hospital accommodation for them and quotes Dr. Hermann Weber that "well-arranged special hospitals for the treatment of consumption can accommodate only 1 sufferer in 1000." Professor Leyden is quoted as calculating the deaths from phthisis in Germany as 170,000 per annum and the number of the living who are suffering from phthisis he estimates at 1,300,000. The fearful mortality in prisons, asylums, and convents from tuberculosis is shown in Dr. Hermann Biggs's reports by copious extracts from well-known authorities on the subject too numerous to be mentioned here; suffice it to say that the death-rate in these institutions from phthisis averages from 38 to 62 per cent. of all deaths.

The first and main point which I want to emphasise is that the public must be educated as to the nature, cause, and curability of phthisis, and taught that by far the most usual method of its dissemination is by dried sputum—tuberculous meat and milk taking a secondary place. It is only by making the public fully alive to the source and danger of the present state of things that they, and through them the Government, can be moved to act, and this can only be done by us as a united profession. Every medical society, association, or organisation should be a nucleus for disseminating knowledge of the more recent views as to the prevention of tuberculosis and its usual origin, and these views should be respectfully but firmly urged on the various corporate bodies, local government boards, county councils, &c., by memorials praying that the public should be instructed by means of pamphlets and *vivâ-voce* teaching. Attention would then be aroused and the medical profession would be given a free hand in the matter, and measures in accordance with medical sanitary science would be promptly adopted. This is no visionary scheme; it has already been acted on and efficiently carried out in America, notably in New York, where notification of phthisis exists, and the public board of health not only affords every facility to medical men for the gratuitous examination of sputum but is able to insist on thorough disinfection of premises in which a victim of phthisis has either lived or died. It also insists on these premises not being let or tenanted until such disinfection has been carried out to the entire satisfaction of the inspector. It also issues for free distribution leaflets and pamphlets in four languages giving instructions to patients and their relatives and friends as to the contagiousness of tuberculosis, its dissemination from dried sputum, together with directions for its disinfection and destruction, and moreover it rigidly enforces an effectual inspection of all meat and milk-supplies for the security of the public against tuberculous meat and milk. If all this can be and is done elsewhere, why can it not be effected in England? Leprosy, plague, and cholera have been almost stamped out in the British Isles, and although it is now almost universally admitted that tuberculosis is a communicable and infectious disease and by far the most fatal to which our race is exposed yet we take no precautions against its spread. Statistics prove it to be the most easily controlled of all the infectious disorders, while it is more fatal in its ravages than all the principal diseases put together. In London alone, with its 4,500,000 inhabitants, tuberculous disease causes upwards of 10,000 deaths annually, the death-rate for London from tuberculosis being one-seventh of the entire death-rate, and the majority of those 10,000 lives might and should have been saved. According to our present knowledge tuberculosis is chiefly disseminated by the dried, pulverised sputum of those suffering from the complaint being inhaled into the lungs of those already susceptible, and this is the point we should constantly impress on the public. We have, of course, a Board of Health, but we need a body such as I have already described in New York, with power not only to lay down sanitary laws but also to enforce them. These are, briefly, compulsory notification of all cases of tuberculosis, stating age and sex, duration of disease, and place of residence; gratuitous examination of sputum; isolation in special hospitals and disinfection of premises; prompt disinfection and destruction of sputum; and rigid inspection of all meat and milk-supplies. The Government of the United States is democratic, but the sanitary measures adopted are sometimes autocratic and the functions performed by sanitary authorities paternal in character. I freely admit that in this country public opinion is not yet ripe for radical measures, but surely a beginning might be made if only our profession put all their united energies into so good a cause. Why should not we adopt the same precautions with regard to tuberculosis that we do not hesitate to enforce in the case of small-pox, scarlet fever, and diphtheria? We should thus, perhaps, become in time, as a profession, not simply medical advisers but a species of "beneficent autocrats" with the power of enforcing our salutary policy in spite of the prejudice, timidity, and sentimental conventionality which step in and ofttimes prevent us from carrying our scientific convictions to a philosophical conclusion. Surely he who robs us of our health is not less guilty than he who robs us of our wealth and both should be equally amenable to the law.

Folkestone.

A METHOD OF ADMINISTERING NITROUS OXIDE GAS FOR THE PRODUCTION OF ANÆSTHESIA, AVOIDING THE USE OF A CLOSED MASK OR OF VALVES.

BY GEORGE FLUX, M.D. BRUX.,

ANÆSTHETIST TO THE GREAT NORTHERN CENTRAL HOSPITAL AND TO THE BRITISH LYING-IN HOSPITAL; ASSISTANT ANÆSTHETIST TO THE DENTAL HOSPITAL OF LONDON; LATE ANÆSTHETIST TO THE NATIONAL DENTAL HOSPITAL.

IT is usually regarded as an accepted fact that the special aim in giving nitrous oxide gas should at first be to exclude air and that in order to achieve this the patient's face must be enclosed in an accurately fitting mask so constructed that respiration can only be carried on through valves and under pressures differing from that of the normal atmosphere. Experience has shown that to get good results with nitrous

Digitized by Google

oxide gas a sufficient supply of oxygen must be provided by nature or art. The old "laughing gas" was impure and when mixed with oxygen produced great excitement; the modern gas, being pure, when mixed with oxygen rarely produces undue excitement, so that the objection to mixing it with air no longer holds good.

I have found that pure nitrous oxide gas administered in the following manner produces most excellent results. The patient being seated in a chair with the head slightly thrown back, a napkin folded to a width corresponding to the height of his face is passed round his head and lightly secured in such a manner that, while the lower border of the napkin is in contact with the chin and lower part of the face, the upper border at a level with the patient's eyes bulges forward several inches so that a cup-like cavity, open at the top and closed at the bottom, is formed. The patient is now ready to receive the gas. The gas is supplied by merely holding the end of the supply pipe over the cup-like cavity, the amount being regulated by a stopcock; the gas by its own weight falls into the cavity, and is thus easily inspired at the normal atmospheric pressure and thoroughly mixed with as much air as the patient requires. At each expiration the patient blows the face-piece nearly empty, and on inspiration breathes both fresh air and fresh gas; it is only necessary to turn on fresh gas when inspiration occurs. I find that from eight to ten gallons of gas are used for a single administration, but with a less porous and a better-fitting face-piece than a folded napkin the consumption should be considerably less.

So far my operations in this direction have been conducted without any specially constructed apparatus, but now that I am convinced of the practicability of the method I am having one made; it consists of a cup-shaped face-piece completely open at the top with a suitable stopcock for regulating the supply of gas.

The number of cases in which I have used this method has so far been limited, but in all of them the most striking feature has been the extreme tranquillity of the patient, who passes easily by almost imperceptible stages from consciousness to anæsthesia and back again to consciousness and has all the appearance of being merely asleep. The face keeps its colour, the breathing continues gentle, and sleep becomes deeper and deeper till the usual signs of anæsthesia appear, lasting from forty-five to sixty seconds, when the patient quietly wakes up. In none of these early cases has there been any jactitation, stertor, or noise, nor any hurrying of respiration, nor any complaint of the slightest feeling of inconvenience to respiration. I have tried this method upon myself and, apart from a sense of drowsiness, I was unaware of any unusual sensation. In addition to the action of the face-piece in conveying the gas to the patient, its being wide open at the top has the great advantage that it enables the whole of the patient's face to be under direct observation and it also adds to his comfort. It allows his respiring under ordinary conditions, thus relieving all sense of oppression; he is free from the transmitted hiss from the gas bottles and from the disturbing bruit of valves, to say nothing of his escaping from the odour which seems inseparable from all ordinary forms of gas apparatus and from the discomfort and risks of breathing into and out of an apparatus which many have used before him.

Old Burlington-street, W.

THE TREATMENT OF RINGWORM OF THE SCALP.

BY H. LYLE, M.R.C.S. ENG.,

SENIOR ASSISTANT SURGEON TO THE HOSPITAL FOR CANCER AND SKIN DISEASES, LIVERPOOL.

THE treatment of ringworm of the scalp, especially if the case has become chronic, is most tedious and tiresome. Much has been written about the subject, but the treatment still remains as unsatisfactory as ever. Dependent as the disease is on the implantation and subsequent growth of the spore of the trichophyton tonsurans it commences as a small spot and generally escapes notice until it has become a patch of more or less considerable size. As this spore has probably been simultaneously implanted at different points the patches are usually multiple, being more or less circular in form and presenting a roughened appearance. The hairs on the infected areas are short and stubbly and are easily removeable. Of course, many cases of ringworm of the scalp are fairly easily cured, but others drag on month after month in spite of every kind of treatment. Among the remedies which have been recommended for this intractable disease are daily epilation and the application of various drugs, some in the form of ointments and others as oils. Formalin has been very highly spoken of, but I have found its application so painful that I no longer employ it. Chrysarobin has been much used alone and in combination, as well as *huile-de-cade* and iodide of sulphur. Oleate of mercury dissolved in olive oil has likewise been extensively tried. Of course, in places where there is a special hospital the medical adviser, disgusted and wearied with the seeming futility of his treatment, can either recommend his patient to a specialist or, if the patient is too poor for that, he can send him to the hospital. But in the country such a course is mostly out of the question and the medical man has to do the best he can.

Hoping that it may be useful to the country practitioner, who has no one to whom to send his chronic cases of ringworm, I venture to lay before the readers of THE LANCET a plan of treatment which I have found most satisfactory. Tired of seeing children come week after week and month after month with no improvement in their condition I determined to try what painting with a solution of silver nitrate would do. Among others on whom I used it I chose two of the most chronic cases which I could find; in one case the patient had been attending hospital twice a week for many months and in the other not quite so long. Neither of these patients had improved much in spite of their long attendance. The usual changes had been rung on the drugs generally employed—namely, ointments, oils, &c. The method I adopted was this. I had the heads entirely shaved and kept so. I scraped each patch with a Volckmann's spoon and then, by means of a piece of cotton wool rolled round the end of a glass rod and tied there, I applied a solution of silver nitrate of the strength of a drachm in an ounce of proof spirit and well rubbed it in. This of course turned all the places of application black. This was done twice a week and after removing the black layer each time (which came off fairly easily) I scraped off as much of the underlying parasitic growth as I could with the spoon before repainting with the solution. The smarting after its use was not much and only lasted a short time. An oil of oleate of mercury, 5 per cent. in strength, was rubbed into the heads night and morning as well. In the two cases which I have mentioned I had to paint almost the entire scalp so large was the extent of the growth. The heads were washed before the application and, as stated above, were kept shaved. Of these two cases after about fourteen weeks of this treatment one is quite well and the other is nearly so. I have tried this method on heads *de novo*, but I have found it very difficult to get the mothers to persevere with the attendance. In all the cases, however, in which I used it the improvement was remarkable. One boy who had numerous patches when he first came under treatment has now (after about fifteen weeks) no spots at all. As the diseased areas became smaller and on the wane I increased the strength of the solution from one drachm of the salt to two drachms to the ounce of spirit, but I always scraped the patches before applying it. I am of opinion that the remedy in addition to the destructive effect of silver nitrate on organic matter acts by depriving the growth of air. I should like to say that I often see cases of alopecia areata which have been sent as tinea. I need hardly remark that the remedy is not likely to be of much use to them.

Liverpool.

EXHIBITION OF OPTICAL AND OTHER INSTRUMENTS AT THE LONDON MANSION HOUSE.—On Monday last, Oct. 3rd, the Lord Mayor opened an exhibition of optical, mathematical, and scientific instruments under the auspices of the Spectacle Makers' Company. Among the objects of interest to be seen are astrolabes of the fourteenth to seventeenth centuries, sun dials from England, France, Germany, Italy, and the maximum and minimum thermometer used by Captain Ross in his various voyages round the world. Among the exhibits of interest to medical men are those of Messrs. W. Harry Cox, Ltd. (electrical and scientific apparatus), Messrs. Raphael and Co., Messrs. R. W. Paul, Messrs. Carpenter and Westley, Messrs. R. and J. Beck, Ltd., and Messrs. George Culver.

ROYAL FREE HOSPITAL.

A CASE OF ACUTE MEMBRANOUS LARYNGITIS IN A CHILD REQUIRING TRACHEOTOMY AND INTUBATION; RECOVERY.

(Under the care of Dr. SAINSBURY.)

THE following case is well worthy of being recorded, especially in connexion with the very similar case reported in THE LANCET of August 13th. Although the failure to find the bacillus of diphtheria is no certain proof of the absence of that disease, yet if the examinations have been careful and numerous we are fully justified in saying that the case is in all probability not diphtheritic. Theoretically it is by no means impossible for an inflammation caused by streptococci to be accompanied by a membranous exudation; all that is required is that the inflammation should be of sufficient intensity to give rise not merely to a "serous" exudation but to an exudation which can coagulate. In the analogous case of inflammation of the serous membranes the degree of coagulability of an exudate varies greatly. There is much to be said in favour of the view of the existence of a membranous laryngitis not due to the Löffler bacillus, but its existence can only be proved by the putting on record of all cases which have been carefully observed and bacteriologically examined. For the notes of the case we are indebted to Mr. Allan C. Parsons, house physician.

A child, aged one year and four months, was admitted to the Royal Free Hospital on April 10th, 1898, at 2 A.M. with difficult and noisy breathing of three days' duration. On examination the patient was found to be suffering from marked laryngeal obstruction, as shown by the stridor on inspiration and sucking in of the lower ribs. There was slight cyanosis and the alæ nasi were working vigorously. The child was breathing 22 to the minute: examination of the lungs revealed nothing abnormal. The pulse-rate was 120 and the heart's action was well maintained. The temperature was 96° F. The fauces were reddened and slightly swollen, but no membrane could be seen. Though the child was restless the general condition was fair and there was no albumin in the urine. The child was isolated with steam-kettle and tent, and at 2.30 P.M. on April 10th 10 c.c. (4000 units) of antitoxin were injected. The same dose was repeated twelve hours later. The child took food very badly and nasal feeding was resorted to. On the day after admission a culture was made from the mucus of the pharynx with a negative result as regards diphtheritic bacilli, streptococci alone being found. By the 13th the general condition of the child had improved considerably, though the breathing was noisy and difficult at times. Nasal feeding was no longer necessary. On the 15th, five days after admission, the child became very restless and suffered from attacks of spasmodic dyspnœa. The cough was dry and croupy in character, and on listening to the chest rhonchi were heard over both lungs. The pulse-rate had increased and the temperature rose to 101°. A second culture was made, but no specific organisms were found. The breathing became more and more difficult and the child was standing up in the cot fighting for breath. An operation was deemed advisable and tracheotomy was accordingly performed on the 16th at midnight. The breathing at once became easier and the child slept for twelve hours after. Three days later the metal tube was replaced by a soft rubber one. About this time some "membrane" was coughed up through the tube, but though a careful bacteriological examination was made no diphtheritic bacilli were found. The child continued quite well and comfortable so long as the tube remained in, but attempts to remove it at once brought on dyspnœa and cyanosis. As this difficulty got worse it was decided to try intubation, therefore on May 2nd the smallest sized O'Dwyer's tube was passed without an anæsthetic. Twelve hours later the tube was removed and the child was seen to be breathing quite naturally through the larynx. From now onwards the child made a rapid recovery and during convalescence iron and strychnine were given. The patient was seen three months after admission, in good health and without any sign of paralysis.

Remarks by Dr. SAINSBURY.—This case presents one or two points of special interest. In the first place it would seem to be an instance of a non-diphtheritic membranous laryngitis arising independently of any direct damage to the part, as by scalding or other form of mechanico-chemical irritation. In favour of this conclusion there are (1) the negative results of cultures taken from the fauces and the direct negative examination of the membrane coughed up; (2) the absence of any albumin in the urine; (3) the absence of any paralytic sequelæ; and (4) the fact that no history pointing to contagion could be obtained. Non-diphtheritic membranous laryngitis, contended for by many, amongst others by Fagge, denied by many others, and in any case regarded as a rare event, would seem to have been present here. In the next place the case is of interest on account of the speedy relief, obtained by intubation, of that troublesome condition which makes it sometimes so difficult to remove the tube after tracheotomy. It is not a question here of discussing the relative merits of intubation and tracheotomy and the case is an instance simply of the value of intubation as a supplement to tracheotomy. Lastly, assuming the case to have been non-diphtheritic, we may note the complete harmlessness of 8000 units of diphtheria antitoxin.

ROYAL CORNWALL INFIRMARY.

TWO CASES OF DISLOCATION OF THE LENS INTO THE ANTERIOR CHAMBER OF THE EYE; REMOVAL.

(Under the care of the late Dr. GEORGE F. HELM.)

THE displacement of the crystalline lens into the anterior chamber of the eye can only occur with a dilated pupil and is certainly much less common than the dislocation into the vitreous. Though cases do occur in which the displacement is not followed by any other ocular disturbance, and the lens may even remain transparent, yet usually the irritation set up requires the removal of the lens, and especially is this advisable if the displaced structure has become opaque. The risk of escape of vitreous in removing the lens is less if the dislocation has taken place into the anterior chamber than if the lens has passed backwards. The second case is of interest as having followed the crude "operations" of the "Indian oculists" who practised in England a few years ago. The operation they performed was evidently the old "couching for cataract."

CASE 1.—A man went to the Royal Cornwall Infirmary stating that three weeks previously he had received a blow on the left malar bone from a piece of stone which he was breaking with a hammer. The eyeball was not struck by the stone. He had experienced terrific pain in the eye. The lens of the left eye was displaced forwards into the anterior chamber. The centre of the lens was quite opaque and was placed obliquely in the anterior chamber, the upper margin being more backward than the lower. The pupil was widely dilated and there was great ciliary injection. The tension was quite + 1. Perception of light was fairly good. The anterior chamber was free from inflammatory products. The patient's consent for an attempt to be made to extract the lens with enucleation to follow if unsuccessful was readily given. A Graefe's knife easily passed across the anterior chamber, the obliquity of the lens facilitating this. A slight escape of vitreous followed the incision, but with a fine scoop Dr. Helm secured the lens and withdrew it. The eye recovered perfectly well and the patient left the infirmary with vision equalling $\frac{6}{36}$ with a convex lens.

CASE 2.—Dr. Helm was consulted in 1891 by a man about his left eye. There was no vision with this eye, which, moreover, was very painful. It was evident that his lens was in the anterior chamber. The history of the eye was as follows. Some years ago the patient had an injury to this eye which caused traumatic cataract. For the cure of this he consulted the "Indian oculists," then in Cornwall, who operated upon it. The pain being so dreadful he begged to be relieved. By means of a Graefe's knife and a scoop

Digitized by Google

Dr. Helm extracted the lens without the loss of any vitreous. The eye progressed perfectly well, but the patient refused any spectacles, being contented with the vision of the other eye.

Remarks by the late Dr. HELM.—The treatment of cases of dislocation forwards of the lens appears to admit of no doubt: (1) the dislocated lens must be removed by extraction—it can be of no use trying to replace it, for the eye does not tolerate even a dislocated lens; but (2) if as the result of the incision of the cornea there follows a considerable loss of vitreous it then becomes a question as to whether it is not best for the ultimate welfare of the patient to enucleate the eyeball. This I was prepared to do in either case supposing that my efforts to extract were not successful. In both the above cases the fact that the lens had become opaque was a decisive reason for extraction. I had an opportunity of examining the instruments which the "Indian oculists" use in the couching of cataracts. They are two in number. Their operation consists, first, in making an incision in the sclerotic behind the ciliary attachment of the iris. This they do with a huge old-fashioned lancet which in their case was rusty and very dirty. Into this incision the second instrument is inserted—viz., a large copper probe with a conical end of the size of a No. 4 Couper's lacrymal probe. This is passed through the pupil at its upper portion and the lens is made to "lie down"—their own words. Sometimes they fail and, as in the instance of the patient in Case 2, the lens slips through the pupil, with the result which I have described.

Reviews and Notices of Books.

Dictionary of National Biography. Edited by SIDNEY LEE. Vol. LIII. Smith—Stanger. London: Smith, Elder, and Co. 1898. Pp. vi. and 486.

THE biographies in this volume include one of Edmund Spenser, the celebrated author of "The Faerie Queene." Spenser was born in London about 1552 and lived in Ireland as a Government official from 1580 to 1598. Of the two poems on which his fame mainly depends, "The Shepheards Calender" was the first to appear in print, the date of publication being 1579. "The Faerie Queene" was issued in two successive portions, the first in 1590 and the second in 1596; the biographers (Professor J. W. Hales and Mr. Sidney Lee) claim for it "a place among English narrative poems not far below the greatest of them—Milton's 'Paradise Lost.'" Spenser died in Westminster in 1599. Adam Smith, well known as the author of the "Theory of Moral Sentiments" and the "Wealth of Nations," was born at Kirkcaldy in Fifeshire in 1723. In 1751 he was appointed Professor of Logic in Glasgow University, and in the following year he was transferred to the chair of Moral Philosophy. He was a patron of James Watt, the inventor of the steam-engine, who was enabled by the University to set up as a mathematical instrument maker in Glasgow. The "Theory of Moral Sentiments" was published in 1759 and the "Wealth of Nations" in 1776. Adam Smith died in 1790.

The biographies of medical men are thirty-two in number. John Flint South was born in London in 1797, studied medicine at St. Thomas's Hospital, having been apprenticed to Henry Cline the younger for the usual sum of £500, and was admitted a member of the Royal College of Surgeons of England in 1819. He held various appointments at St. Thomas's Hospital and was eventually, in 1841, made full surgeon, a post which he resigned in 1863. He was also in 1841 elected a member of the Council of the Royal College of Surgeons of England and in 1843 was nominated one of the first Fellows of the College. He acted as Professor of Human Anatomy and Surgery in the College for 1845 and he was Hunterian orator in 1844. "His oration made no mention of the man he was called upon to eulogise; he gave a retrospect of the history of medicine, beginning at so early a period that the time expired before he had arrived at the eighteenth century." Mr. South was President of the Royal College of Surgeons of England in 1851 and again in 1860; he resigned his official connexion with the College in 1873. He published several original works and translations of treatises by Otto and von Chelius. The last twenty years of his life were spent in gathering materials for a history of English surgery. The project was on too large a scale to enable him to make much progress, but his work was edited by Mr. D'Arcy Power in 1886 under the title of "Memorials of the Craft of Surgery." He died at Blackheath Park in 1882. Samuel Solly was born in London in 1805. In 1822 he was articled to Benjamin Travers, surgeon to St. Thomas's Hospital, and was one of the last of the surgeons to a London hospital who succeeded to his post by the payment of a large apprenticeship fee. He was admitted a Member of the Royal College of Surgeons of England in 1828. From 1833 to 1839 he was lecturer on anatomy and physiology in the medical school of St. Thomas's Hospital; he was appointed assistant surgeon to the hospital in 1841; twelve years later he became full surgeon and was appointed lecturer on surgery. Elected a Fellow of the Royal College of Surgeons of England in 1843, he became a member of the Council in 1856 and was twice a vice-president. He was admitted a Fellow of the Royal Society in 1836 and became President of the Royal Medical and Chirurgical Society in 1867–68. He died in 1871. James Spence was born in Edinburgh in 1812. He studied medicine in Edinburgh University and in the extra-mural school and in 1832 he received the diploma of the Royal College of Surgeons of Edinburgh, having previously spent some time in Paris studying anatomy and surgery. As soon as he was qualified he made two voyages to Calcutta and on his return to Edinburgh he passed about 22 years teaching anatomy and surgery in the extra-mural school until in 1864 he became Professor of Surgery in the University. He was appointed a Fellow of the Royal College of Surgeons of Edinburgh in 1849 and was President in 1867 and 1868. He was made surgeon-in-ordinary to the Queen in Scotland in 1865 and became a member of the General Medical Council in 1881 as representative of the Royal College of Surgeons of Edinburgh. He died in 1882. The writer of the biography (Mr. D'Arcy Power) says of him: "Spence must be reckoned among the great operating surgeons who have rendered Edinburgh famous throughout the world. Like Liston, Fergusson, and Syme, he had so intimate a knowledge of anatomy that every step in a difficult operation was foreseen. ..... He was essentially a conservative surgeon, and, like his great contemporary, Sir William Scovell Savory, he maintained that in skilled hands the simpler methods of the older school were preferable to, and gave as good results as, the more complicated system adopted by the disciples of the antiseptic school of Lister." John Spurgin, born in Essex in 1797, studied at Cambridge University and in Edinburgh, graduating at Cambridge as M.D. in 1825. He became a Fellow of the Royal College of Physicians of London in 1826, Censor in 1829, conciliarius in 1851–53 and 1862–64. He delivered the Harveian Oration in 1851 and the College lectures on Materia Medica in 1852. He enjoyed an extensive practice, was physician to the Foundling Hospital and St. Mark's Hospital, and died in 1866. Andrew Smith, born in Roxburghshire in 1797, studied medicine at Edinburgh University and graduated as M.D. in 1819. From 1821 to 1837 he was an army medical officer in Cape Colony, during which time he superintended exploring expeditions in Central Africa, collected the materials for his "Illustrations of the Zoology of South Africa," and wrote papers on the Bushmen. It was due to his representation and counsel that Natal became a colony of the British Crown. Returning to England in 1837, he was made Inspector-General and

Digitized by Google

Superintendent of the Army Medical Department in 1851 and was nominated Director-General of the Army and Ordnance Medical Departments in 1853. The evidence laid before the Sebastopol and other committees did much to vindicate his reputation as an administrator during the Crimean campaign. He was created K.C.B. in 1858 and died in 1872. Aquilla Smith, born in county Tipperary in 1806, studied medicine at Trinity College, Dublin, and received the degree of M.D. *honoris causâ* in 1839. He was Professor of Materia Medica and Pharmacy in the School of Physic from 1864 to 1881, and from 1851 to 1890 he represented the Royal College of Physicians of Ireland in the General Medical Council. He was a copious writer on antiquarian subjects, mainly numismatics. He died in 1890. Edward Smith, born in Derbyshire about 1818, was educated at Queen's College, Birmingham, and graduated at London University as M.D. in 1843. In 1853 he was appointed lecturer on anatomy at Charing-cross Hospital and in 1861 assistant physician to the Brompton Hospital for Consumption. His first researches were on questions connected with physiological chemistry, several memoirs on which were presented to the Royal Society, and he was admitted F.R.S. in 1860. Dietetics formed the subject of most of his subsequent literary work, and after being consulted by the Government on Poor-law and prison dietaries he was appointed medical officer of the Poor-law board. He died in 1874. John Gordon Smith, born in 1792, was educated at Edinburgh, graduated at the University there in 1810, and was present at the battle of Waterloo as surgeon to the 12th Lancers. He lectured on medical jurisprudence at the Royal Institution of Great Britain in 1825 and 1826 and in 1829 was elected the first Professor of Medical Jurisprudence at the London University (now University College) in Gower-street. None of the licensing bodies in London required any evidence of instruction in forensic medicine and there was consequently no class. Smith lectured for two years and then resigned his office. For a time he edited the *London Medical Repository*. He died in a debtors' prison, after fifteen months' confinement, in September, 1833. Thomas Southwood Smith, born in Somerset in 1788, studied medicine in Edinburgh and graduated as M.D. at the University there in 1816. From 1812 to 1820 he was a Unitarian preacher, partly in Edinburgh and partly in Yeovil, Somerset. In 1820 he removed to London and entered on an active career as a writer for the Useful Knowledge Society and as a pioneer of sanitary reform. In 1832 he was placed on the Central Board for Inquiring into the Condition of Factory Children, an inquiry the precursor of the existing Factory Acts, and in 1848 was appointed medical member of the "General Board of Health." He died at Florence in 1861. William Tylor Smith, born in 1815 near Bristol, was educated at the Bristol School of Medicine and graduated as M.D. at London University in 1848. When St. Mary's Hospital was founded he was appointed obstetric physician and lecturer on obstetrics and taught there for the allotted term of twenty years. "He was long engaged upon the editorial staff of THE LANCET, at first only as an occasional contributor, but soon as one of its sub-editors. Among his contributions were valuable papers 'On Quacks and Quackery' and a series of biographical sketches of the leading physicians and surgeons of the metropolis." His Manual of Obstetrics published in 1858 immediately became, and long remained, the favourite textbook in this country. He raised the position of obstetric medicine, not only by his teaching, oral and written, but by the foundation of the Obstetrical Society of London, of which he was elected President in 1860. He died in 1873. John Snow was born at York in 1813 and studied medicine in London. In 1838 he was admitted a Member of the Royal College of Surgeons of England and in 1844 he graduated as M.D. at London University. To him is due the theory that cholera is communicated by means of a contaminated water-supply, and his essay upon the Mode of Communication of Cholera, which was first published in 1849, was awarded by the Institute of France a prize of £1200. In 1846 he demonstrated the use of ether as an anæsthetic in St. George's Hospital and the ether practice in London came almost entirely into his hands. He also administered chloroform to the Queen at the birth of Prince Leopold in 1853 and again at the birth of Princess Beatrice in 1857. He died in 1858.

Two names of medical men who have won a purely literary celebrity deserve to be mentioned. Albert Richard Smith, son of a surgeon, was born in Surrey in 1816, studied at the Middlesex Hospital, and became qualified in 1838 as M.R.C.S. Eng. and L.S.A. He commenced medical practice but was soon diverted from it to the writing of numerous novels, sketches, dramas, extravaganzas, entertainments at the Egyptian Hall, contributions to *Punch*, &c. He died in 1860. Tobias George Smollett was born in 1721, near the town of Bonhill, Dumbartonshire, studied medicine at Glasgow University, and after serving four years as a surgeon in the Royal Navy settled in practice in London. His first novel, "Roderick Random," appeared in 1748; his second, "Peregrine Pickle," in 1751; and his third, "Ferdinand Count Fathom," in 1753. In 1770 he took a house near Leghorn, where "Humphrey Clinker" was written the same year, and where he died in 1771.

LIBRARY TABLE.

A Treatise on the Science and Practice of Midwifery. By W. S. PLAYFAIR, M.D. Edin., LL.D. St. And., F.R.C.P. Lond. Ninth edition, with over 200 Illustrations and 8 Plates. Two vols., demy 8vo. London: Smith, Elder and Co. 1898. Price 28*s*.—It is pleasing to see from the appearance of a ninth edition of Playfair's Midwifery that this favourite and well-known text-book still holds its own amongst the numerous competitors with which at the present time it has to contend. The reason is, however, not far to seek when we see how thoroughly this new edition has been brought up to date. The author has been fortunate in accomplishing this without unduly increasing the number of pages, only some 36 having been added to the whole, so that the work still retains its handy form and size. Two new plates and some 17 new illustrations have been introduced. The plates are one of a section of the frozen body towards the termination of the second stage of labour, after Barbour, and one illustrating streptococci, after Bumm and Crookshank. Dr. Playfair has secured the valuable assistance of Dr. Eden in revising the section upon Conception and Generation, and the outcome is a chapter of great interest, including the results of all the most recent work upon the subject. Amongst other changes we note that the treatment of cases of ectopic gestation has been revised in accordance with the latest views. The author is in favour of treating cases where the tube has ruptured extra-peritoneally and where operative interference is called for by Kelly's method of vaginal incision followed by plugging of the cavity with iodoform gauze, and subsequent irrigation with antiseptic lotions. In the chapter upon Ovarian Tumours causing Obstruction during Labour Dr. Playfair quotes Dr. McKerron's recent paper upon the subject, and while in the main agreeing with his conclusions thinks that in cases of small tumours vaginal extirpation might often be possible. The cases recently reported of vaginal Cæsarean section followed by total extirpation of the carcinomatous uterus at full term show that tumours of considerable size can safely be extracted in this way owing to the great relaxation of the passages which occurs in connexion with pregnancy. It is possible, therefore, that vaginal ovariotomy may turn out to be a successful mode of treatment where small ovarian cysts impacted in the pelvis are causing obstruction to labour.

Digitized by Google

In Dr. McKerron's paper 3 cases treated in this way are recorded, all of which recovered. Many other portions of the text besides those which we have noticed bear evidence as to the care with which the whole has been revised, and the book well maintains its reputation of being one of the most readable and reliable works upon the subject of which it treats.

Elements of Sanitary Law. By ALICE RAVENHILL, Lecturer to the National Health Society. With an Introduction by Sir RICHARD T. THORNE. London: The Sanitary Publishing Co. Price 6*d.*—This is an unpretending little pamphlet of 44 pages containing various provisions from the Public Health Acts set out in plain and simple language. All the references are given so that authority for the statements can be easily looked up if necessary. Our sanitary laws are very good as a whole and the only fault we have to find with them is that in too many cases they are permissive, that is to say, the sanitary authorities are told that they *may* do this or that instead of *must* do it. Concerning one form of negligence which has been much in evidence of late, the magistrates have shown a weakness in convicting or, if they have convicted, have inflicted ridiculously light penalties, which is certainly not the way to get the nuisance abated. Miss Ravenhill has done a very good work in thus laying before the ordinary citizen the rules and regulations which make, if properly carried out, for his health.

Analytical Records
FROM
THE LANCET LABORATORY.

(1) GRANULATED GLYCERO-PHOSPHATES (ROBIN); (2) KOLA BINSCE; AND (3) PEPTONATE OF IRON (ROBIN).

(AGENCY: C. JOZKAU, 49, HAYMARKET.)

As is well known, the glycero-phosphates in the form of calcium and sodium salts have been administered with excellent results in improving the general nutrition of the nervous system. Lecithin yields on suitable chemical treatment and by the process of digestion also the calcium salt of glycero-phosphoric acid and this has doubtless suggested its value in neurasthenia and as a specific restorative in general debility. The preparation described above occurs in granular form and contains both sodium and calcium salts. It is a beautifully white, clean, crystalline powder, which is quite stable in character. It possesses a slightly sweetish taste. Chemically pure glycero-phosphate of lime may be had also in the form of tablets which are slightly effervescent. Each tablet contains about 5 gr. of the salt. "Kola Binsce" is essentially a granulated preparation of the glycero-phosphates which, however, in addition, contains an important amount of the active principles of the kola nut. We found that by extracting the compound with chloroform a distinct quantity of caffeine was obtained. This is to some extent a proof of the statement that kola nut is part of the combination. The grains are delicately coffee-coloured. According to the formula "kola binsce" should be a valuable tonic combination. Peptonate of iron is well known and the preparation submitted to us gave evidence of care in its elaboration so as to exclude the objectionable properties common to the ordinary iron salts. Pure peptonate of iron is not astringent and does not disturb the digestive functions and while it is known as the most easily assimilated form of iron it does not produce constipation.

KLOESTERLE MINERAL WATER.

(FIEBER BROTHERS, 14, MINCING-LANE, E.C.)

Kloesterle water is drawn from a spring near Carlsbad, Bohemia. It contains a slight excess of free carbonic acid gas and a notable proportion of alkaline salts, with which is lithia in small but distinct quantity. The proportion of common salt is small and does not exceed 0·064 gramme per litre. The alkalinity of the water is equal to 1·26 grammes of carbonate of soda per litre. Carbonate of soda indeed is the chief constituent, the lime and magnesium salts occurring in trifling quantities. It is on this account probably that the water is so peculiarly soft to the palate. The saline residue obtained on evaporating a few ounces of the water gave a marked lithium line when examined spectroscopically. The water presents an interesting composition and is quite free from organic matter. It ranks with those alkaline carbonated waters of which a course is known to be useful in certain gastric disorders, while it also exercises a beneficial action on the urinary functions.

VICTORIA VIOLETS SOAP.

(EVANS GADD AND CO., 97, 98, 99, AND 100, FORE-STREET, EXETER.)

The materials in this soap are well chosen, pure and combined in proper proportion. We could trace no injurious ingredients or foreign substances, minute tests for the presence of free alkali being attended with negative results The soap is stained apple green and possesses an agreeable odour of violets. It lathers somewhat freely and is pleasantly emollient.

FALIÈRES PHOSPHATINE.

(AGENCY: 64, HOLBORN-VIADUCT, E.C.)

Though so far little known in this country this preparation appears to have been employed as a valuable infants' and invalids' food on the continent. It is essentially a farinaceous food prepared by a special process which adds to its digestibility and it is enriched by the addition of very finely comminuted phosphate of lime and is finally sterilised. According to our analysis its composition is as follows: moisture, 9·66 per cent.; mineral salts, 1·16 per cent.; nitrogenous constituents, 9·0 per cent.; dextrine sugars and soluble starch, 35·03 per cent.; insoluble starch, cocoa, &c., 41·53 per cent.; and fat, 3·62 per cent. Over one-third part therefore is soluble in cold water, a result which is largely due to the action of careful baking. The flavour is somewhat sweet with a suggestion of cocoa and vanilla. The statement is quite correct that the phosphate of lime is present in a highly comminuted form and in such a condition as to offer no difficulty to assimilation. Added to milk it affords a food admirably adapted for the requirements of infants. Phosphatine, in fact, supplies just those important elements in nutrition upon which the proper growth and development of infants so much depend.

HOOBA DIGESTIVE TEA.

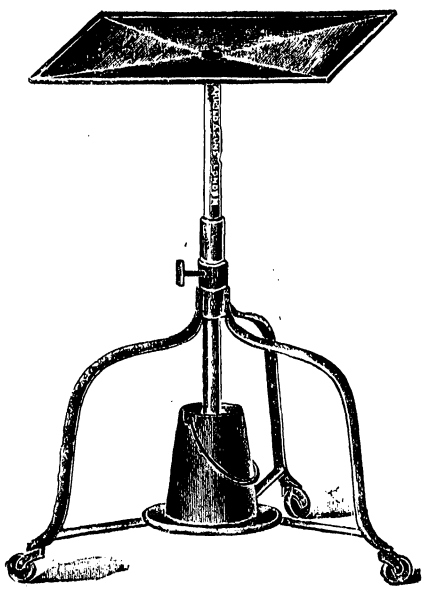
(THE HOOBA TEA CO., DUNSTER HOUSE, MINCING-LANE, E.C.)

Why this tea is described as "digestive" we are not certain. It yields normal results of analysis and apparently has undergone no special treatment. The mineral matter was quite an average amount, being 5·5 per cent. The alkalinity of the ash was equal to 1·53 per cent. calculated as potash K_2O. On complete exhaustion with hot water the astringent matters given up were normal in amount. An infusion prepared in the ordinary way was agreeable and delicate in character and free from the harsh properties of powerful Indian tea. It is a good specimen of tea and probably a specially selected leaf, but we do not consider that it possesses properties of a more "digestive" character than choice Ceylon or China growths.

(1) RIOJA BRILLANTE PALOMA (RED WINE); AND (2) LAS NAVAS (WHITE WINE).

(P. DE OTADUY AND CO., 20, HIGH HOLBORN, W.C.)

On analysis these specimens of Spanish wine gave the following results:—Rioja Brillante Paloma: extractives,



Digitized by Google

1·66 per cent.; mineral matter, 0·21 per cent.; tartaric acid, 0·72 per cent.; acetic acid, 0·15 per cent.; sugar, 0·10 per cent.; alcohol, by weight 9·36 per cent., by volume 11·61 per cent.; equal to proof spirit, 20·35 per cent. Las Navas: extractives, 1·65 per cent.; mineral matter, 0·22 per cent.; tartaric acid, 0·53 per cent.; acetic acid, 0·19 per cent.; sugar, 0·31 per cent.; alcohol, by weight 13·15 per cent., by volume 16·24 per cent.; equal to proof spirit, 28·46 per cent. There can be little doubt of the purity of these wines. They are quite sound in character, practically free from volatile acidity, and somewhat "full-bodied," but devoid of any excess of sugar. In this regard the red wine is practically free, while the white wine contains an insignificant amount. Neither is an old wine, but both promise an excellent development. The red wine, from the point of view of alcoholic strength, is lighter in character than the white wine. Spain is a country with a prolific production of grapes, and the above specimens are representative of some amongst the excellent and genuine wines which are now imported to this country and which are deservedly increasing in popular favour.

New Inventions.

A SURGICAL DRESSING-TABLE.

MESSRS. ARNOLD AND SONS have made an antiseptic surgical dressing-table at my suggestion for use in the consulting-room as well as in the operating theatre. It is constructed throughout of enamelled iron and runs easily on rubber-tyred wheels. The table can be raised or lowered to a convenient height and fixed in the required position by a screw. It is drained somewhat like a post-mortem table, and

all fluid passes down a central tube into a convenient receiver which can readily be removed. In private practice one has often to attend to surgical cases; and for dressing wounds and in minor operations I have found the table very convenient. In the operating-theatre it can be run alongside the operating-table and raised to any convenient height for the requirements of the surgeon or his assistants. I think it would be found very useful for military hospitals and on field service, as it can be easily carried about and is practically unbreakable. It can be made in various sizes.

HERBERT W. G. MACLEOD, M.D., M.S. Edin.,
Streatham, S.W. Late Her Majesty's B.M.S.

THE MEDICAL SCHOOLS.

SCHOLARSHIPS AND PRIZEMEN.

Charing-cross Hospital Medical School.—The following Entrance Scholarships have been awarded: Livingstone Scholarship (100 gs.), to Mr. G. E. Bellamy; Huxley Scholarship (55 gs.), to Mr. B. R. Bickford; and Universities Scholarships (each 60 gs.), to Mr. H. C. Gabb and Mr. B. G. Fiddian. Entrance Scholarships have also been awarded to Mr. R. H. Cooper (60 gs.), Mr. D. M. Davies (40 gs.), and Mr. T. Law (30 gs.), and Exhibitions of 30 gs. each to Mr. A. C. Ingram, Mr. G. O. Lambert, and Mr. B. R. Lloyd.

Guy's Hospital Medical School.—The following Entrance Scholarships and Certificates have been awarded: Scholarship for University students: Mr. H. S. French, Christ Church, Oxford, £50; Mr. E. J. Claxton, King's College, Cambridge, Certificate. Open Science Scholarships: Mr. E. H. B. Milsom, Guy's Hospital Medical School, £150; Mr. F. Rogerson, Guy's Hospital Medical School, and Mr. N. J. Spriggs, private study, equal, £30 each; Mr. H. D. Smart, Guy's Hospital Medical School, Certificate; and Mr. H. S. Brown, Guy's Hospital Medical School, Certificate. Open Arts Scholarships: Mr. R. F. MacDonald, Bancroft's School, £100; Mr. W. G. Taylor, Aberdeen University, £50; Mr. J. W. Walton, Folkestone Grammar School, £30; Mr. G. Hamilton, Aske's School, New Cross, Certificate; Mr. G. A. Horton, University Tutorial College, Certificate; and Mr. J. James, St. Bees School, Certificate.

London Hospital Medical College.—The following are the results of the examinations for the Entrance Scholarships: Price Scholarship, £120, Mr. F. W. Jones; Epsom Scholarship, £126, Mr. Colmer; Price University Scholarship, £60, Mr. Bousfield; Science Scholarship, £60, Mr. J. W. Fox; and Science Scholarship, £30, Mr. Rainforth.

Middlesex Hospital Medical School.—The First and Second Entrance Scholarships have been awarded to Mr. W. Cameron Macaulay and Mr. William Gordon Taylor, M.A., respectively. The Leopold Hudson prize and the Lyell gold medal have been awarded to Mr. A. J. Knowlton; the Hetley clinical prize to Mr. P. Gardiner and Mr. B. H. Slater; and the John Murray gold medal and scholarship to Mr. C. G. Pugh. Mr. H. R. Dutton, Mr. C. E. Lakin, Mr. C. H. Reisman, and Mr. C. G. Pugh have been elected Exhibitioners.

St. Mary's Hospital Medical School.—The following Entrance Scholarships have been awarded:—Natural Science: Mr. E. W. C. Bradfield, £144; Mr. N. T. Spriggs, £78 15*s.*; Mr. H. A. Haig, £78 15*s.*; Mr. J. H. Burgess, £52 10*s.*; and Mr. E. L. Ash, £52 10*s.* University Scholarships: Mr. H. E. Corbin, B.Sc., £57 15*s.*; Mr. W. H. Clayton Greene, £57 15*s.*; and Mr. W. V. Shaw, B.A., £57 15*s.*

St. Thomas's Hospital Medical School.—The First Entrance Scholarship and the William Tite Scholarship have been awarded to Mr. W. H. Harwood-Yarred the University Scholarship to Mr. F. C. Eve, and the Peacock Scholarship to Mr. C. N. Sears. Entrance Scholarships have also been awarded to Mr. Charles Michael Roberts, Scholarship, £150; Mr. Harry Mellor Woodcock, Scholarship, £60; Mr. Charles Hugh Latham, Exhibition, £20. The Mead Medal for Practical Medicine to Mr. E. F. Buzzard, the Cheselden Medal for Surgery to Mr. S. O. Bingham, and the Bristowe Medal for Pathology to Mr. A. D. Sikes. Medals have also been awarded to Mr. C. W. Pilcher, Mr. A. Bevan, and Mr. H. E. Hewitt.

University College, London.—The following Medical Entrance Scholarships have been awarded: Mr. H. A. Haig, 131 guineas; Mr. M. Stewart Smith, 55 guineas; Mr. W. M. Sadler, 55 guineas.

DEVON COUNTY ASYLUM.—There were nearly forty applications for the appointment of medical superintendent to the Devon County Asylum, Exminster, rendered vacant by the resignation of Dr. Symes Saunders. Six of this number were selected, and finally Mr. Arthur Nathaniel Davis, L.R.C.P., L.R.C.S., L.M. Edin., who has for the last seven years been medical superintendent of the Plymouth Borough Asylum, Ivybridge, was appointed.

THE LANCET.

LONDON: SATURDAY, OCTOBER 8, 1898.

IT was a happy inspiration which led the authorities of Charing Cross Hospital to invite Professor VIRCHOW to deliver the Huxley lecture on the occasion of the opening of the medical session. They could not have better honoured the name of the eminent man whose medical education was obtained in their institution than by linking it in this manner with that of the foremost living exponent of pathological science. HUXLEY, whose life was devoted to the search after truth, whose keen intellect dispersed so many dogmas and illumined the obscure places of biological problems, and whose strenuous and single-minded advocacy did so much to establish the most notable scientific conception of his time; and VIRCHOW, whose name and fame have been known to all the world for more than half a century as those of one who, gifted like HUXLEY with more than common insight, applied the teachings of biology to the elucidation of morbid processes and effected for pathology as great a change almost as Darwinism did for the science of life,—it is well that these two names should thus be brought into conjunction; whilst on many other grounds there could not be found one better fitted to give such a lecture than Professor VIRCHOW, whose wide knowledge and liberal sympathies entitle him to speak with an almost unique authority on the progress of medical science. For who is there among us who can tell of his own knowledge the wondrous tale which has been unfolded before the eyes of this master during the years in which he has been engaged in scientific investigation? Nor has he been a mere passive onlooker whilst the tide of discovery has been bringing fresh treasures to his feet. All the world knows that had it not been for Professor VIRCHOW pathological science would have remained in a state of crudity and of vague speculation. The fundamental idea of the "cellular pathology" which he promulgated awakened a new interest in, and gave a new meaning to, morbid processes. It remains essentially unshaken to the present day, although in matters of detail modifications have been made from time to time, many of these accessions to knowledge having been made by men directly inspired by Professor VIRCHOW himself.

Our position to-day in regard to this question is that it dominates all our views of organic life. We can no more conceive of organised structures, exhibiting vital phenomena, whether the simplest or the most complex, without reference to the "cell" as the unit, than we can conceive of the sun apart from light and heat. Nevertheless, the biologist and the pathologist are bound to confess their inability to solve the whole problem of existence. It was much, very much, to impress on the imagination the fact that the cell is the simplest form in which life is manifested; that the changes wrought in the organism by disease can be referred to changes in which these ultimate living elements take part, but the nature of life itself baffles the keenest intelligence. Professor VIRCHOW alluded to the overthrow of the theory of "free-cell-formation," which, as he said, amounted to a revival of the older doctrine of spontaneous generation. He defined the organism as a "social" not an "individual" mechanism, made up of cells themselves composed of inert chemical substances; but he did not pretend to say—and herein we have the best example of the ignorance of the wisest—to what the cell owes its life. All we do know and all we can say is that since life first appeared on this earth there has been a continuous and unbroken ever-extending chain of living elements derived from pre-existing elements similarly endowed. The application of the doctrine to pathology was, as we have said, Professor VIRCHOW'S great service, and nowhere has it been more surely confirmed than in the domain of new growths. It may be that the actual cause of these abnormal and destructive formations will some day be discovered; but whatever it be it cannot upset the certain knowledge which we have of their intimate structure and their origin from pre-existing elements in the body. That the problems of hereditary transmission, whether of actual characteristics or deformities, or of tendencies to disease, are better explained by virtue of the potencies contained within the parent cells than by any fancied changes in the blood or fluids of the body, can hardly be questioned. These fluids are but the media whereby the tissue cells obtain their nutriment and whereto they part with their products. The cells themselves are the active and living entities which exist in the ovum before the formation of blood and lymph and are directly derived from the two sexual elements without the conjunction of which no new organism can be built up.

Perhaps the most interesting portion of this lecture—if one part could be said to be of greater interest than another—was the exposition of parasitism and the great extension which has been given to this in the discovery of the minute parasitic agents which excite the infective diseases. Professor VIRCHOW did well to remind us that the reaction of the tissues and organs to the bacterial poisons forms an essential part of these diseases, and he, perhaps wisely, bade us remember that there may be some infections in which bacteria have no share. But to the incalculable gains to humanity arising from the recognition of these agencies he bore ample witness, and instanced the work of LISTER and the introduction of serum therapeutics as evidence of this. We must not conclude without expressing our gratification that Professor VIRCHOW should have selected this theme for his address, which is sure to dwell in the memory of the young students who formed the essential part of his audience. Certainly they could have no better examples to follow in their pursuit of medical science than those set by HUXLEY and VIRCHOW.

THE military despatch of Lord KITCHENER of Khartoum on the battle of Omdurman was published last week in the *London Gazette*, accompanied by one from Sir FRANCIS GRENFELL, the General Commanding in Egypt, and an Order from Lord WOLSELEY, the Commander-in-Chief. The

Digitized by Google

General Officer Commanding in Egypt having previously held the post of Sirdar of the Egyptian Army, and having had ample experience of Soudan warfare, was peculiarly fitted to form a correct estimate of the difficulties which his successor had to encounter and of the admirable skill and success with which these had been overcome. Sir FRANCIS GRENFELL tersely sums up the subject and the situation, together with the impression he had derived from the perusal of the despatch describing the latest phases of the Soudan campaign and the final action on Sept. 2nd last. The Sirdar, he says, in his despatch recounts in brief, simple terms the events of the closing phase of one of the most successful campaigns ever conducted by a British general against a savage foe, resulting in the capture of Omdurman, th destruction of the Dervish power in the Soudan, and the reopening of the waterway to the equatorial provinces.

The Sirdar in all he did was thorough. He had, no doubt, already had experience of the tactics and fierce intrepidity of his foe and an intimate knowledge of the country, but what was perhaps more to the purpose he possessed the initiative capacity and judgment requisite to turn these to the best account. Having left nothing to chance it appeared that the campaign would be run with the regularity of machinery; and, that being the case, he foresaw and boldly declared what the end would be—and he was right!

It is eminently gratifying to find that a general has been found endowed with such high military qualities and the necessary force of character to have the courage of his opinions, endowed at the same time with a spirit of justice and even generosity in regard to all those who had so largely contributed to the success of his undertaking. Nor should it be forgotten that, from a political standpoint also, he has apparently acted throughout with excellent discretion and judgment. The medical services—British and Egyptian—are to be congratulated on the handsome way in which they are mentioned in his despatch.

"The Medical Department was administered with ability and skill by Surgeon-General TAYLOR, principal medical officer, who was well assisted by Colonel MACNAMARA, whilst the medical organisation of the Egyptian army fully maintained its previous excellent reputation, under the direction of Lieutenant-Colonel GALLWEY and his staff. The general medical arrangements were all that could have been desired and I believe the minimum of pain and maximum of comfort procurable on active service in this country was attained by the unremitting energy, untiring zeal, and devotion to their duty of the entire medical staff."

We are glad to notice that while the zeal and administrative capacity of Surgeon-General TAYLOR, as principal medical officer, are appreciatively recognised, the services of Colonel MACNAMARA are not forgotten, for he had all along laboured hard and well at his work. It was also fitting that Sir FRANCIS GRENFELL, in calling attention to the arduous duties performed by the staff and departments at Cairo, should have included the name of Surgeon-General H. S. MUIR, upon whom much extra responsibility and work must have fallen in connexion with the Soudan expedition. The previous Nile expedition for the rescue of GORDON—the most chivalric figure of this century—at Khartoum was unhappily, as we all know to our cost, unsuccessful. The Egyptian war of 1882 was, however, most successful, and notwithstanding that almost everything had to be sacrificed to celerity of movement on that occasion, the surgical and medical results attained were splendid. Still, the medical service was very differently treated then—"but that's another story." We may allude, in conclusion, to one gratifying feature in the Sirdar's despatch which we do not remember to have seen before—namely, the frequent mention of non-commissioned officers and privates, and among them of men of the Royal Army Medical Corps, in the long list of names appended to the despatch.

DIFFERENT minds will be differently affected by the various discourses upon subjects more or less intimately connected with the medical calling, as given in the Introductory Addresses which we report to-day There certainly is a great variety of topics. Professor MICHAEL FOSTER, to whose address we shall refer on another occasion, restricted himself very much to one point—the nature of a university as distinguished from that of a college or a school. But for the most part the lecturers allowed themselves a free scope, descanting on various subjects, from the value of a "good bedside manner" to the deepest questions of medical science and medical duty. After all, it does not greatly matter on these occasions what particular subject is taken. The medical art is so wide in its relations, it concerns human life so deeply, it so affects States and armies and society itself, it touches so nearly questions of philosophy and morals and politics, that from whatever point of view the introductory lecturer may look at his theme he can scarcely fail to excite interest in his audience and in that larger audience outside, to which many of the addresses are obviously directed. Medical matters are evidently becoming of more and more interest to the public. With all its criticism of the profession and in spite of the tendency of certain minor sections to regard themselves as equal without medical guidance to cope with the problems of disease, whether affecting the nation or the individual, there is a growing perception of the importance of the medical calling and of everything affecting the efficiency of the schools in which its followers are trained.

We do not now attempt to discuss or even summarise all the points raised in addresses of such varied scope, but we select a few which appear to us to be of special interest and importance. We note with much satisfaction that several of the lecturers referred to the subject of over-examination. Sir JAMES CRICHTON BROWNE, who may be supposed to speak on this subject with special authority, spoke of the stupidity manufactured by examinations. Dr. CULLINGWORTH expressed entire agreement with Mr. TEALE'S expressed opinion that the medical student is over-examined. We are sure that students will be grateful to such authorities for speaking so clearly on this subject, though there would have been greater cause for gratitude if some practical remedies for an evil which is now generally admitted had been indicated. The students who are now beginning another session must not count upon any immediate change in the system of examinations which has now grown to such proportions.

Digitized by Google

This system cannot be altered in a day or by any individual body; but with a consensus of opinion against it it is certain to be modified. We are not apologists for ignorance and still less for idleness in students. We are under no delusions as to the justice with which many of them are "referred" for further periods of study. But it is clear from the opening addresses this year and from other sources of evidence that Mr. TEALE has a large following in thinking that the existing system of examinations is excessive and injurious. For all fair examination few students will be unprepared who enter into the spirit of the words of the oath of HIPPOCRATES, which might well be hung in the room of every student for the remainder of the session, or, for that matter, for his lifetime. He will attain to no age and to no position in which the spirit of that oath will not be helpful to him. But more modern wisdom than that of HIPPOCRATES will be found in this year's addresses, and the observance of but a fraction of the advice which they contain will make all study interesting and will do much to secure success in practice as well as in examinations. There is a danger, said Dr. VOELCKER, in his address at Middlesex Hospital, of students forgetting their own essential share in the success of their studies. There is a risk in the very care with which every lesson and demonstration is now elaborated for them. Every fact in anatomy and every feature of disease should be ascertained by the observation of the student and not merely read about in a book. The risk of prepared food for infants, with its rachitic results, is not more real than is the risk that work done for students in a way which leaves them no work to do for themselves will destroy their power of working.

Amid much that is dispiriting in the circumstances of the profession and in the attitude of the public it is impossible not to refer to the responsible nature and wide functions of the medical life. These points were very strikingly brought out in the address of Dr. H. A. CALEY, who spoke at length on the preventive as distinguished from the curative function of medicine. People are apt to think that the preventive function applies only to infectious and notifiable diseases. But the duty of the true physician is far wider than this. He must impress upon his patients that degeneration as well as infection can be prevented. Neither will he find this impression easy to convey, for there is a singular want of intelligence in the public in this respect. It will take great pains and go to great expense to arrest the degeneration of a tooth, as Dr. CALEY says, while it will take no thought for the degeneration of an aorta or a kidney. We may hope that with improved education such apathy will not exist and that the public will learn to prize a physician who averts disease as much as it respects him who heals. The more the practitioner fits himself for such high duties, the more in the long run will he be respected by the public and by his patients, and the more will he be differentiated from all quacks and nostrum-dealers.

At St. George's Hospital Mr. TURNER chose a very practical topic. He exposed with much force the abuse of medical charities and denounced with much justice the cult of altruism which is pursued at other people's expense. The question is a very large one and one calling for the serious consideration of hospital surgeons and physicians. We hope that Mr. TURNER and his colleagues will take other opportunities of raising the subject.

Annotations.

"Ne quid nimis."

THE DANGEROUS TRADES COMMITTEE.

A FURTHER blue book containing the third interim report of the Departmental Committee appointed to inquire into, and report upon, certain miscellaneous dangerous trades has been issued. From a glance at the contents of the report it is clear that the committee have not yet inquired into the use of lead in certain arts and of its effect upon the operatives concerned. It may fairly be presumed, since this subject has been brought so prominently into public notice during the last year, that the committee will devote more than ordinary attention to it and extend their inquiries to the potteries. For this they will, we anticipate, await the findings of Dr. T. E. Thorpe and Dr. Thomas Oliver, who have recently been appointed as experts to inquire into the conditions obtaining at the potteries where lead glaze is employed. Dr. Oliver serves also on the Dangerous Trades Committee. The report under notice deals with file cutting, galvanised iron works, sole stitching by American machinery, glass polishing, the use of converters in metal works, the manufacture and use of grindstones, the testing of bottles by compressed air, and the "ending and mending" in velvet works. In regard to the industry of file cutting the committee find that the situation is full of difficulty and complexity. The spirit of the law is now constantly violated, and they venture confidently to recommend legislation on certain lines sketched in the report which, if adopted, will provide a means of adequately safe-guarding the health of persons engaged in this industry. In regard to galvanised iron works the committee do not consider the industry one which should be scheduled as a dangerous trade and while making certain observations they do not think it necessary to recommend special rules for its control. In the same way there is little evidence to show that any specific injury to health is caused by the American method of sole stitching. Several recommendations are drawn up in regard to providing better conditions for the operatives engaged in glass polishing, the chief and perhaps most important of which is that every facility for washing should be provided by the employers and that no man should be allowed to eat his meal without having previously washed his face and hands. The dangers attending the operations connected with the use of converters, as in the Bessemer process of steel manufacture, have been thoroughly gone into. The chief danger appears to be the spilling of molten metal and recommendations guarding the workers against this are drawn up. A considerable proportion of the report is devoted to the dangers of working involved in the manufacture and use of grindstones. Here the chief risk appears to be the "flying" of grindstones of defective composition. Accordingly it is recommended that the stone should be thoroughly tested before being employed for grinding or smoothing purposes. To this end attention should be paid to the detection of cracks and flaws by special means. In regard to the testing of bottles by compressed air the committee have not found any serious record of accident, but they remark that it is desirable that legal powers should be given to Her Majesty's inspectors to require the adoption and use everywhere of gauze veils and

Digitized by Google

gauntlets. Lastly, the committee find that the operations attending the "ending and mending" in velvet works are without injury to health, so that the committee have requested and obtained the permission of the Secretary of State to have this trade withdrawn from their reference.

THE WINTER SESSION OF THE MEDICAL SOCIETIES.

DURING the present month the various medical societies of London will reopen their doors. The first to resume will be the Medical Society, the opening meeting of which will take place on Monday, the 10th inst. The newly elected president, Mr. Edmund Owen, will deliver an inaugural address, and Dr. Allchin will read a paper on Some Considerations Preliminary to the Study of Dyspepsia. The secretaries have already secured papers from Mr. Marmaduke Sheild, Dr. Sidney Martin, Dr. Sidney Phillips, Mr. Pearce Gould, and others to be read early in the session. The Royal Medical and Chirurgical Society will open on the 25th inst. under the presidency of Mr. Thomas Bryant. Some important papers are promised but at present no arrangements have been made for any special discussions such as that on enteric fever which attracted such large audiences last session. The Clinical Society will meet for the first time on the 14th inst., when the president, Mr. John Langton, will deliver the opening address which he postponed last year. The second meeting, on the 28th inst., will be a clinical evening. The Pathological Society, with Dr. J. F. Payne for the second time in the chair, will start the work of the session on the 18th inst.

THE INFECTIVENESS OF MILK IMPORTED INTO MANCHESTER.

A REPORT recently presented to the sanitary authorities of Manchester by Dr. James Niven, the medical officer of health, upon the Bacteriological Condition of Imported Milk with Special Reference to Tuberculosis, reveals a very serious state of matters. Samples were taken at railway stations and other places to the number of 100 and of these 93 were carefully examined by Professor Delépine. Of these 93, 17, or over 18 per cent., were proved to be tuberculous. The next step was to examine the condition of the cows at the incriminated farms and the results of the investigation confirmed in a most remarkable way the bacteriological examination. 16 farms were investigated and in 14 of these one or more cows were found to have indurated udders, presumably tuberculous. In a previous report presented to the committee it was mentioned that on the examination of one cow with tuberculin the udder, which had not previously been found to be tuberculous, gave a marked local reaction. It is, in fact, evident that an udder may be infectious and yet give no palpable indications of disease, a consideration which may well explain those instances in which Bang and others have found the milk to be infective without any appreciable disease of the udder. The report goes on to advise the sanitary authorities to apply to Manchester the provisions existing in Glasgow for the safeguarding of the purity of milk. These provisions, which are under the Glasgow Police Amendment Act, 1890, give power to sanitary authorities to enter byres, to compel the owners of cows to assist the medical officer in his investigations, to make it necessary for intimation to be given of diseased cows, and to provide penalties for selling the milk of diseased cows. The question of tuberculosis among dairy cattle is a very serious one. Although we have had a Royal Commission on the matter the only person who appears to have even attempted to act upon it is Lord Vernon. Medical officers all over the country are agreed upon the necessity of steps being taken to minimise the plague, and we may well ask, if a small and poor country like Denmark can do what she has done to stamp out tuberculosis in cattle, why should not Great Britain and Ireland do the same?

COMPARATIVE LONGEVITY IN THE COUNTRIES OF EUROPE.

ACCORDING to the *Bulletin Général de Thérapeutique* the average duration of life amongst the chief nations of Europe is as follows, the figures being based upon the bills of mortality for the decade 1881-90: Sweden and Norway, 50 years; England, 45 years and 3 months; Belgium, 44 years and 11 months; Switzerland, 44 years and 4 months; France, 43 years and 6 months; Austria, 39 years and 8 months; Prussia and Italy, 39 years; Bavaria, 36 years; and Spain, 32 years and 4 months.

STREET RUFFIANISM.

HOOLIGANISM has culminated, as is only natural, in murder. Early on the morning of Oct. 2nd a policeman on point duty near the Regent's Canal heard sounds of quarrelling in Wilmer-gardens. On proceeding to the spot he found a crowd of persons angrily disputing. Picking out an apparent ringleader he attempted to arrest him, when a man promptly stabbed him. Two more policemen then came up and arrested the alleged assailant. The injured constable was taken to the Metropolitan Hospital where he died. Tinkering with this sort of thing is no use. Short, sharp, and decisive measures are necessary; the police should be better armed, with revolvers if necessary. In all cases of brutal assault, whether on ordinary citizens or the police, magistrates should have power to order—or rather should be compelled to order—a sound flogging. Amusements, free drinks, free libraries, free education, six months' holiday at the seaside paid for by people who work, and other softening influences, may possibly be considered at a later date; but in the meantime the wild beasts of London should be treated as harmful animals are elsewhere and suppressed. In saying this it must not be supposed that we are insensible to the lack of healthy amusement for portions of the community which is evident in London. Mrs. Ormiston Chant points out in a very sensible letter in the *Times* of Oct. 4th that there is no reason why a "hall" should not supply a bright, cheerful, and elevating entertainment. Everyone will allow that within the last twenty years the standard of entertainment by the halls has been enormously raised. Mrs. Chant's plea for a good and cheap restaurant to be opened in connexion with a music hall is a very good one. But before ameliorating the ruffian's general condition he must be made to understand by the medium of bodily suffering that "Hooliganism" will not be allowed any longer.

INFANTILE DIARRHŒA.

AN article on the Summer Diarrhœa of Infants by Dr. G. Variot in the *Journal de Clinique et de Thérapeutique Infantiles* of Sept. 22nd derives an especial interest from the prevalence of that disease during the recent hot weather. The writer, as might be expected, has limited his attention practically to one form of diarrhœa, that which is associated with lactic fermentation and which is naturally most prevalent during a warm summer or the after-glow of a mild autumn. It is true that Dr. Variot's views on the influence of a high external temperature are at least novel, since he regards the pathological changes in the intestine which give rise to this form of diarrhœa as due to actual insolation. He believes that those changes are thus produced in the case of infants nourished on sterilised milk as well as in those fed on milk not sterilised and even in

Digitized by Google

those suckled at the breast. He admits nevertheless that the loose motions observed in the last case are unattended by any of the local or general distress associated with fermentative or choleraic diarrhœas. The main argument in his paper, moreover, is employed to promote the use of cows' milk sterilised by heat as opposed to that not so treated where the breast is not available, and this on the ground of its freedom from morbific organisms prior to its use. In support of this argument he quotes a series of 110 recorded cases of diarrhœa in children fed on sterilised milk which gave a total mortality of 9. He considers that even that low figure should not have been reached had the children, out-patients at a dispensary in Paris, been tended by their parents with a more intelligent accuracy and amid sanitary surroundings. He alleges that the majority of fatal cases occurring under his care at the Hôpital Trousseau were patients brought up on ordinary sterilised milk. From these facts he draws the only possible conclusion—namely, that any approach to certainty in the prevention of infantile diarrhœa can only be attained by sterilisation of the milk used. Exposure to a temperature of 115°C. will suffice for this purpose, but 100°, which is with many the customary standard, will not suffice. Unfortunately sterilised milk is somewhat expensive, but its place may commonly be filled with little if any risk to the consumer by ordinary milk delivered fresh and boiled. It is also to be remembered that however sterile the milk may be it is constantly liable to contamination by the feeding-bottle or other vehicle of administration. The importance of keeping this thoroughly cleansed, of using different bottles alternately, of frequently boiling them and any tubes attached to them, can be hardly exaggerated. We are pleased to observe, as a result of constant reiteration by medical men and other instructed persons, a marked extension of knowledge on this subject. To this more than to any other agency we must look for the prevention of what is probably the most deadly scourge of infant life. Whatever importance we may attribute to the action of heat on the body or to variations in subsoil moisture it is, we believe, indisputable that such influences operate—certainly as a rule—not on the body itself so much as by vitiating the natural food of infancy.

THE NICE ADJUSTMENT OF CORPORAL PUNISHMENT.

IN the *Times* of Oct. 4th there is a short letter by an anthropologist who thinly veils his identity under the initials "F. G.," pointing out that in estimating the amount of pain inflicted by corporal punishment it must be borne in mind: (1) that the worse the criminal the less sensitive he is to pain; and (2) that the pain produced does not vary with the force of the blow, but "approximately, according to Weber's law, four times as heavy a blow only produces about twice as much pain." "F. G." does not state what conclusions or modifications of existing practice should be deduced from this, but we may be allowed to point out a fallacy with regard to each of the points which he raises. It is quite true that the habitual criminals and degenerates studied by Lombroso were proved to be less sensitive than normal individuals, but we doubt if the after-part of a boy who for amusement risks wrecking a train by placing stones on the line is less sensitive than that of his better-behaved schoolmates. And there are many first offenders who would certainly feel a whipping as acutely as any average man. With regard to the deduction from Weber's law, even assuming that the law holds with stimuli of such intensity, "F. G." seems to be thinking merely of the sensation produced by the contact of the birch or "cat" with the skin. But every boy who has been caned knows that the after-smart is a very serious item in the punishment, and with the heavier blows, owing to the injury of the deeper tissues and the resulting inflammation, the total amount of suffering produced would certainly be greater than that theoretically deduced by an application of Weber's law. The frequent use of the "cat," on account of the injuries and lacerations it produces, is repugnant to modern ideas, but a cane or a good birch wielded by a strong arm will inflict very severe punishment without serious risk of injury. We fear that physiological psychology has not advanced sufficiently to enable even an expert to adjudge so many units of suffering, and at present the matter may safely be left to the common sense and discretion of the judges and magistrates, who might wisely, we think, have a much wider discretion in the matter than they at present possess.

THE PLAGUE IN INDIA.

WE regret to state that there is at the present time no sign of improvement in regard to bubonic plague in India. According to the latest telegrams the plague returns for the week ending Oct. 1st show a serious recrudescence of the disease in Bombay city, 209 deaths being reported, as compared with 127 in the previous week. In Bombay Presidency the number of deaths increased from 3000 in the previous week to 4000, chiefly in Dharwar, Belgaum, Satara, and Kolhapur. Calcutta is free, and only one death is reported from Karachi, but the plague is becoming epidemic in Bangalore city, where 124 deaths have occurred. 3 cases are reported from Hyderabad State, 3 from Wallunden in the Punjab, and 16 in 4 districts of Madras. The quarantine and severely repressive measures which have been favoured hitherto have, as we all know, given rise to a great deal of native discontent and opposition, and as they have not been attended with the successful results which were anticipated or hoped for, the Government of India has had to relax them. The progress of the epidemic in India is conforming to what has been the history of plague elsewhere in the past and in China, the enforcement of land quarantine is attended with serious hardships and is, moreover, simply impracticable; the natives would prefer to run the risk of contracting plague to submitting to the severely repressive measures hitherto enforced. As a matter of policy the Government is justified in relaxing them under the circumstances in which it is placed.

THE FIFTH INTERNATIONAL CONGRESS OF HYDROLOGY, CLIMATOLOGY, AND MEDICAL GEOLOGY.

THIS Congress was held during last and part of the present week at Liége (Belgium), under the patronage of H.R.H. the Crown Prince of Belgium and the presidency of M. de Bruyn, Minister of Agriculture. The Congress was well attended by representatives of various nationalities. Many important communications were read and discussed in the various sections, but the most interesting was a conference given before the whole Congress by Walthere Spring, the distinguished Professor of Chemistry at the University of Liége, on the Colours of Natural Waters, in which he showed experimentally that the true colour of pure water is blue, as in the Lake of Geneva, and that this colour is the colour proper to the water and is not due to a mere reflection from the surface or to suspended particles in the water; and that when pure water has a very slight cloudiness due to the presence of finely divided nearly white or colourless particles in suspension, even if these are absolutely colourless, as in the case of very finely divided rock crystal, a yellow tint is given to the water, which, together with the natural blue proper to the water itself, produces a green colour, as in the cases of the lakes of Neufchatel and of Constance. He remarked that

Digitized by Google

it had been noted by various observers that the waters of certain lakes ordinarily green became occasionally absolutely colourless, and this he showed was due to the washing into the lakes of a fine mud of a reddish tint, due to oxide of iron, which neutralised the green colour of the water, rendering it for the time being perfectly colourless. Interesting excursions were undertaken to view the bathing establishments and sanitary arrangements of Ostend and Middlekerke, Spa, Chaudfontaine, and Aix-la-Chapelle. The Sanitary Institute was represented at the Congress by Dr. Corfield, the Professor of Hygiene and Public Health at University College, London, who was elected an honorary vice-president of the Congress and was also appointed the English member of an international committee which was formed for the purpose of inquiry into the means to be adopted for the preservation of the purity of the sources of natural mineral waters.

RAIN-MAKING.

THE drought still continues but the bright clear sky during the present week has disappeared, very little sunshine has been recorded, and the British Isles have been wrapped in clouds. But the clouds seem loath to part with their load of precious water, a reluctancy which must be most exasperating to water directors and water engineers. The atmospheric pressure is high and the conditions have been such as to militate against the coalescing and ultimate descent of the particles of water which are so near at hand in large quantity and yet apparently beyond realisation. Scientific research has not been, so far as we are aware, seriously turned to the possibility of tapping the clouds, but in these days when it is considered feasible by the leaders of science to derive the food of man indirectly from the air the suggestion is not so absurd as it might seem. Ordinary raindrops are formed by the coalescing of a number of the smaller particles which compose cloud. Can, therefore, no means be devised of effecting this coalition, of uniting the smaller particles into particles which at length become so large as to drop to the earth in the form of a blessed rain? The water companies might devote a sum of money towards the practical investigation of this matter or at any rate might institute a committee of inquiry of scientific men with a view to discussing the possibility of being able to induce a result on the lines indicated.

THE COMPARATIVE ETIOLOGY OF DIPHTHERIA.

THERE is no section of comparative pathology of such great importance to the medical practitioner as that which deals with the interchanges of disease between man and the lower animals. A series of observations recently collected by the French Conseil supérieur d'Hygiène and quoted in the *Journal de Clinique et de Thérapeutique Infantiles* of Sept. 22nd, 1898, is therefore of particular interest. The subject under examination is diphtheria and the facts recorded are at least significant. From these it appears that the cat is especially liable to contract this disease and is also necessarily a ready medium for its propagation. Other animals, however, are also liable to it. Thus Gerhardt relates the case of a number of fowls imported into a village near Baden which on arrival developed signs of a disease resembling diphtheria, half of them dying from it. 4 cats which lived among them died from the same disease and 4 out of 6 attendants at the poultry farm suffered severely in like manner. No case occurred in the village itself. Another case is mentioned by Dr. R. Jacobi in which 5 children had diphtheria and 3 kittens which had played with them during their illness died with false membrane on the pharynx. In another instance recorded by Dr. Bruce Low a cat appeared to have carried diphtheria to children. It is noteworthy that the bacillus of Klebs and Löffler cultivated by these observers in the rabbit has given rise to the usual signs of diphtheria, including the subsequent paralysis, and that the observations of Klein on the cat have confirmed their results. Such facts as these are certainly not without meaning when we consider to how large an extent the lives and habits of children are associated with those of their various domestic pets. They may also serve to explain the occurrence of some sporadic cases of diphtheria for which no recognisable cause can be found, but where it is learnt after a time that a sick rabbit or cat was being nursed for a time before the child's illness appeared. It would seem also that in some cases a connexion exists between the yards or kennels in which animals are housed and the occurrence of tonsillar sore-throat in adjacent dwellings. We would commend these considerations to the attention of practitioners and of local sanitary officials, more especially since that which happens in the propagation of diphtheria probably occurs also in the case of other infectious diseases.

THE OUTGOING LORD MAYOR.

WE wish to add a few words to the vote of thanks which the Corporation of the City of London has accorded to Lieutenant-Colonel H. D. Davies, M.P., Lord Mayor, on the occasion of the election of his successor, Sir John Voce Moore. The Lord Mayor in his reply to the thanks of his brother aldermen modestly omitted reference to his hospitality at the Mansion House, but there is one circumstance about this hospitality which calls for a few words of reminiscence. By the medical profession the year of office of Lieutenant-Colonel H. D. Davies, M.P., will be remembered as the year when the City of London through their Lord Mayor publicly honoured the medical profession by inviting to dinner at the Mansion House the presidents of the Royal Colleges and other representative members of the medical profession. This was the first time that the medical profession had received attention from the chief magistrate of the City of London and we owe Lieutenant-Colonel Davies thanks for the precedent and for his graceful hospitality.

COMPLETE RUPTURE OF THE TRACHEA.

AN instance of this rare lesion occurred recently in a man, aged seventy-three years, who was struck by a lift on the back of the head as he was looking down the shaft, with the result that he was knocked down, breaking his sternum. He survived the accident in St. George's Hospital fourteen days, and at the necropsy it was found that the trachea was torn completely across. Although the injury is very rare many cases have been recorded in medical literature. The cause of the accident has generally been a severe blow or the passage of a cartwheel over the throat; in one case it was due to a forcible bending backwards of the head. Urgent dyspnœa and much subcutaneous emphysema are the usual symptoms and death generally occurs within a short time, but, though death is the common termination, recovery has ensued in at least 3 cases—in 2, recorded by Lang and Wagner, without tracheotomy, and in 1, recorded by Lauenstein, in which the trachea had to be opened. It is not improbable that in the case referred to above the fatal result was due to the other injuries sustained rather than to the rupture of the trachea.

PROFESSOR KOCH ON MALARIA.

OUR Rome correspondent writes: "After forty days' unremitting work in the clinical offices of the Santo Spirito Hospital and in the laboratories of the Public Health Department, Professor Koch, on Saturday evening (Oct. 1st), took grateful leave of the Premier (General Pelloux) and the Minister of Public Instruction (Dr. Baccelli), who had

Digitized by Google

aided him so materially in his researches, and, accompanied by his coadjutors, Professor Pfeiffer and Professor Kossel, started direct for Berlin. One of the objects he had in view was to ascertain how far the Italian malaria coincides with the tropical form of the same malady, and he has satisfied himself that in all essentials they are identical. He has also been able to indicate properties hitherto unnoticed in the pathogenic germ of malaria as found external to man—properties possessing a distinct prophylactic value towards limiting the diffusion of the malady if not in arresting it at its point of origin. He has, however, to supplement this part of his researches by others on the same lines, and with this object he intends to return to Italy in the spring of 1899. So far he has found nothing to add on the clinical side of the subject; and the Roman school do not disguise their satisfaction at this frank testimony to the practical worth of their painstaking contributions to treatment. They, in turn, are profuse in their acknowledgments of Professor Koch's scientific elucidation of points hitherto left obscure and are grateful for the impulse he has given to the investigation of problems the solution of which seems now 'within measurable distance.'"

THE ROYAL COMMISSION ON SEWAGE DISPOSAL.

THE Royal Commission which has been appointed to study and report on the question of sewage disposal is now engaged in visiting a number of sewage works. Recently the members of the Commission were in Exeter, where they thoroughly examined the "septic tank" process which has for some considerable time past been dealing with a portion of the sewage of Exeter, and they also inspected the same process in operation at the country seat of Lord Iddesleigh, chairman of the Commission, a few miles from Exeter. The Commissioners have inspected the Manchester Sewage Works at Davyhulme, and also the works at Oldham, at Chorley, and at Rochdale. We understand that shortly after these visits are completed the Commission will resume its work of taking evidence in London and of inaugurating a series of scientific experiments on its own account. The Commissioners engaged in these inspections have been Lord Iddesleigh, Sir Richard Thorne, General Carey, Dr. Russell, Professor M. Foster, Professor Ramsay, Colonel Harding, Mr. Killick, and Mr. Cotton.

THE LOCAL GOVERNMENT BOARD FOR SCOTLAND: THE NEW MEDICAL MEMBER.

DR. JAMES B. RUSSELL, the distinguished medical officer of health of Glasgow, has been appointed to the important post of medical member of the Local Government Board for Scotland. The long and valuable services which Dr. Russell has rendered to sanitation in Glasgow and in Scotland are well worthy of the highest honour and reward which it is in the power of the Government to bestow. Dr. Russell was appointed to the health officership of Glasgow on the retirement from that post of Professor (now Sir William) Gairdner in 1872, and before that time he had been in the service of the city as physician to its fever and small-pox hospitals. He had much to do with the huge municipal improvement scheme which has so greatly and so beneficially changed the face of Glasgow and he was among the earliest to demonstrate on a large scale the conveyance of infectious disease by means of milk-supply. In all the literature of small-pox and vaccination there is perhaps no finer monograph than his "Study of 972 Cases of Small-pox," published in 1872. Many of his writings are among the classics of public health literature and it is difficult to say whether they are more distinguished by the true spirit of the sanitary reformer or by their writer's rare mastery of the English language. Dr. Russell will bring to his new duties a unique experience in Scottish sanitary administration and he will find before him a field well worthy of the exercise of his highest powers. While very much has been done within the last few years to improve the condition both of the large cities and of the rural districts of Scotland, more yet remains to be done, and many of the smaller burghs are, sanitarily speaking, still untouched. Dr. Russell's post will therefore be no sinecure and it would, indeed, be impossible to imagine him making a sinecure of any post. Not seldom it falls to a new official to map out his own sphere of duty and to inform those with whom he is brought most closely into contact as to the true scope and bearings of his own work. Dr. Russell may quite conceivably meet with this experience, and if so there is no one to whose views more weight will be given by those who are in authority. The office to which he has been appointed is a great one and in his hands it will be greatly magnified. In wishing him God-speed we venture to think that we are expressing the sincere desire of every member of the public health service of Scotland.

STREET NOISES.

TWO new by-laws passed by the London County Council for the better regulation of street noises became law on Oct. 1st. The first deals with steam organs, shooting galleries, roundabouts and the like, and provides that they shall not be used or played in any street or on any land adjoining thereto to the annoyance of residents or passengers or to the obstruction or danger of traffic. The second by-law deals with noisy animals, to secure the removal or abatement of which a somewhat complicated process has to be gone through. These by-laws are small mercies but they are something to be thankful for. They leave untouched the piano organ, the German band, the Salvation Army, and that greatest curse of all, the newspaper "runner" and the wandering voice which yells "Winner" almost incessantly from two until six P.M. The publication of a "Winner" card apart from a newspaper is a new torment. The immunity accorded to the newspaper fiend is a blessing for which Londoners have to thank Professor Stuart in the main, for it was owing to his opposition that the admirable by-law introduced by the Council in the summer was defeated. The wandering costermonger is comparatively harmless and fills a useful place in the economy of London. But newspapers can be sold and are sold every day and all day in the streets without howling, therefore there is no reason why the streets should resemble the parrot-house at the Zoological Gardens. But we sincerely congratulate the Council on having attempted to deal with this nuisance, and even have hopes that before very long the selfishness of those who consider that everyone has a right to annoy anybody else will be overcome. If the objectors to the by-law were compelled to work in the Strand or Piccadilly-circus for a time they would change their tune. Meantime we must possess our souls in patience.

THE GREIG SMITH MEMORIAL THEATRE AT BRISTOL ROYAL INFIRMARY.

THE Greig Smith memorial operation theatre was opened by Sir William MacCormac, President of the Royal College of Surgeons of England, in the presence of a large gathering of the citizens on Sept. 30th. The new operation theatre stands on the site of the old one and consists of a principal operation theatre with students' gallery, smaller operation theatre, anæsthetic room, and surgeons' room, also a small ophthalmic operation room. The size of the principal theatre is 21 ft. 4 in. by 15 ft. 6 in. and 26 ft. 6 in. high; a bronze medallion of the late Mr. Greig Smith has been inserted

Digitized by Google

in a prominent position of the wall. The cost of the undertaking has been about £2700. The High Sheriff (Mr. Richardson Cross, F.R.C.S. Eng.) presided at the ceremony and amongst others present were the Duke and Duchess of Beaufort, the Dean of Bristol, Sir W. H. Wills, M.P., and Mr. J. S. Fry. Sir William MacCormac, in the course of an interesting address, said that it gave him much pleasure to open the beautiful new operation theatre; it was worthy of their ancient infirmary, which was one of the oldest in the country out of London. Sir William McCormac added that not only Bristol, but England—surgery, indeed, everywhere—deplored the premature loss of Greig Smith. He was a great surgeon and a modest man. His indomitable energy wore out the machine at the early age of forty-three years, but his work on abdominal surgery lived after him and would continue to live. At the conclusion of the address the Duke of Beaufort proposed a vote of thanks to Sir William MacCormac; this was seconded by Dr. Shingleton Smith and carried with hearty applause.

HONOURS FOR THE PRINCE OF WALES'S MEDICAL ADVISERS.

SIR WILLIAM MACCORMAC, Bart., and Sir Francis Laking have been appointed Knights Commander of the Royal Victorian Order, and Mr. A. D. Fripp and Fleet-Surgeon A. G. Delmege, M.D., have been appointed Members of the Fourth Class of the same Order, in recognition of their services in connexion with the recent accident met with by H.R.H. the Prince of Wales. It may be well to remind our readers that the Royal Victorian Order is bestowed upon "such persons, being subjects of the British Crown, as may have rendered extraordinary, important, or personal service to Her Majesty, her heirs and successors, and who have merited Her Majesty's royal favour." In the case of Sir William Mac Cormac, additional pleasure was, we are sure, given to the recipient by the fact that the Order was graciously bestowed upon him by Her Majesty personally. As far as we know only two other medical men are members of this Order—namely, Dr. William Allen Sturge and Dr. Henry Charles Woods, Deputy Inspector-General, R.N.

THE DINNER TO PROFESSOR VIRCHOW.

THE large and influential gathering, representative of all departments of the medical profession of Great Britain and Ireland—assembled at the Whitehall Rooms on Wednesday evening to do honour to Professor Virchow—embodied something more than the spontaneous homage which all men delight to render to one who has achieved great things. This dinner was no mere complimentary function, as was evident from the tone of the speeches which were made. It was the recognition by our profession of the inestimable services rendered to science by the distinguished guest, and also a tribute of personal attachment to him as a man whose life and character cannot but evoke as much affection as admiration. Very fittingly did Lord Lister, whose occupancy of the chair was most appropriate, propose the health of "Our honoured and beloved master, Professor Virchow"—terms which express so well the relationship which he bears to the whole medical world. For justifiably proud as Professor Virchow may well be of the many eminent pupils—some too early lost to science and the world—who have reflected a lustre on his personal teaching, he must be still prouder at the thought that there is not one of the medical fraternity who has not been influenced by his work. Lord Lister, in proposing the toast of the evening, dwelt very happily upon the versatility of the genius of the distinguished guest, his eminence as a pathologist being equalled by his reputation as an anthropologist and antiquarian, whilst during his whole career he has been prominent in the field of politics, where his voice has ever been raised in defence of liberty, truth, and righteousness. Loud and long-continued cheers, mingled with "Hochs," accompanied the drinking of this toast, and were renewed as Professor Virchow rose to reply, which he did in a speech full of expression of attachment to England—"the land of civil and religious liberty"—and to Englishmen, with especial and appropriate allusion to Huxley whose name is held in such high honour in German scientific circles. Equally happy were the speeches made by all the other eminent men selected for this purpose. Sir William Broadbent's allusion to the high state of medical organisation in the army; Surgeon-General Jameson's testimony to the enormous gains to life by the application of antiseptic surgery in the field; Sir Samuel Wilks's reference to the late Dr. Chance, the translator of Virchow's memorable book; Professor Chiene's reminder of the studies of John Goodsir; and finally Sir William Turner's well-chosen remarks in proposing the health of the chairman, these and many another feature of the evening will make it remembered as one of the most successful reunions of our profession which may be said to have inaugurated the medical session. The best thanks of all present must be due to those who so well organised the meeting—Mr. Andrew Clark, Dr. Rose Bradford, and Mr. D'Arcy Power.

THE REPORTED CARRIAGE ACCIDENT TO THE QUEEN.

WE are glad to be able to state on excellent authority that Her Majesty did not meet with any carriage accident as has been erroneously reported and that she is happily quite well.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE Harveian Oration will be delivered by Sir Dyce Duckworth on Tuesday afternoon, Oct. 18th, 1898, at 4 o'clock. Dr. W. M. Ord will deliver the Bradshaw Lecture on Thursday, Nov. 10th, at 5 o'clock P.M., his subject being Myxœdema and Allied Conditions.

THE report of the committee appointed by the Treasury to consider the desirability of establishing a National Physical Laboratory has been issued. The committee consider that the principles underlying the proposal to establish such a laboratory have been tested on a small scale at the Kew Observatory with most satisfactory results. They also record the high opinion which the Royal Society enjoys among practical workers, for they report that "nearly all the witnesses expressed the opinion that those interested in industry as well as persons devoted to the study of pure science would be willing that the Royal Society should be ultimately responsible for the proposed institution" provided that industry were suitably represented on the governing board.

A WINTER course of lectures will be delivered at the West-end Hospital for Diseases of the Nervous System, Welbeck-street, W., on Tuesdays, at 4 P.M., throughout October, November, and December. The course will consist of demonstration of cases of special clinical interest and will begin on Oct. 11th. The fee for the course is one guinea, and further particulars, cards of admission, &c., may be obtained from the hon. secretary of the Post-Graduation Course, 60, Upper Berkeley-street, W.

AT Cheltenham recently, where some 20 antivaccinationists presented themselves, the Bench refused to be "satisfied" with anything less than a sworn declaration and the question

Digitized by Google

there has been narrowed down to whether the fee of 6*d*. for administering the oath and 1*s*. for the certificate can be legally exacted. It is said that this point is to be tested, but the mere fact that objection is taken to these charges should help to open the eyes of the public to the eagerness of opponents of vaccination in searching for grievances. It will hardly be easy, we fancy, to get up much sympathy for martyrdoms due to refusal to pay the eighteenpenny fees of local courts.

THE Lettsomian Lectures of the Medical Society of London will be delivered on Feb. 6th, Feb. 20th, and March 6th, 1899, by Dr. Samuel West, who has announced as his subject "Some of the Clinical Aspects of Granular Kidney." The Annual Oration of the Society will be delivered on May 15th, 1899, by Mr. Alban Doran.

A SYSTEMATIC course of lectures and demonstrations for sanitary inspectors has been arranged at King's College, London, and the introductory lecture will be given by Dr. W. J. Simpson on Friday, Oct. 14th, at 8 P.M., when the chair will be taken by Mr. T. McKinnon Wood, Chairman of the London County Council.

THE second Hunterian Society's lecture will be delivered by Dr. J. F. Payne on Wednesday, Oct. 12th, at the London Institution, Finsbury-circus, at 8.30 P.M. Dr. Payne will take for his subject "The Increase of Cancer." Members of the medical profession are invited to attend.

THE demonstrations of cases at the Clinical Museum were resumed on Wednesday last, at 4 o'clock P.M., and will be continued weekly at the same hour. Patients should be there at 3.30. All members of the profession are invited.

MESSRS. G. JERRARD AND CO., of 107, Regent-street, announce that they have taken a photograph of Professor Virchow. Some of our readers may like to possess a portrait of the eminent pathologist.

THE Duke of Cambridge will open some time in December the new Kingston-on-Thames Victoria Jubilee Hospital, the site for which his Royal Highness presented to the borough.

WE are asked to announce that the Thursday afternoon lectures at the Hospital for Sick Children, Great Ormond-street, are free to all qualified medical practitioners.

DR. H. B. DONKIN has been appointed a Commissioner of Prisons for England and Wales in place of Captain W. J. Stopford, C.B., retired.

SHEFFIELD SCHOOL OF MEDICINE.—Dr. Dyson vice-president of the University College of Sheffield, delivered the introductory address in connexion with the opening of this school of medicine. Referring to the Vaccination Act he said its principal aims—to provide calf lymph and to facilitate the operation—had his hearty support. The much-discussed conscience clause was the one about which the fiercest contest raged. He was glad he was not a magistrate to have to adjudicate on this clause. In medical treatment he found it sometimes extremely difficult to diagnose a real subjective symptom, such as pain in the back, from an unreal one, and he felt sure many magistrates would have difficulty in diagnosing the real conscientious objection. If the profession were polled he thought there would be a large majority against this clause. The general opinion was that the clause was a retrograde step. The experiment was risky and the profession disclaimed any responsibility if an epidemic of small-pox occurred.

FOOD- AND WATER-SUPPLY AND TRADE NUISANCES IN THE ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD (1897-98).

THE twenty-seventh annual report of the Local Government Board was published last week and we may proceed to deal with three interesting sections contained therein, embracing subjects which have come more or less prominently before the public of late. Probably the question of the adulteration of food will shortly become the subject of debate by the Houses of Parliament with the view of amending the present Sale of Food and Drugs Act (1875).

THE SALE OF FOOD AND DRUGS ACT.

The annual report of the Local Government Board has become during recent years of greater interest in connexion with the Sale of Food and Drugs Act owing to the deliberations of a Parliamentary Committee which concluded its inquiry last year and presented its recommendations to the House of Commons. On more than one occasion has a Bill as the outcome of this inquiry been brought in, but no progress has been made. It is confidently expected, however, that a Bill will be introduced next session which will embody, to some extent at any rate, the recommendations of this committee and so strengthen the present Act as to reduce the practice of fraud and adulteration in all its branches to as low a figure as legislation can be hoped to accomplish. The yearly report of the Local Government Board on this branch of public health administration shows the direction in which the Act works satisfactorily and the direction in which it does not. We have again and again expressed the opinion that the failure of the Act in many particulars has in a great number of instances been the result of the negligence of the authorities to avail themselves of its provisions. Invariably when pressure has been brought to bear upon the local authorities to make use of the powers vested in them the rate of adulteration has been very materially diminished. But, as the present report shows, there are still some districts in which the Sale of Food and Drugs Act is allowed to remain inoperative. In eight jurisdictions no action whatever was taken under the Act, while in seventeen districts the number of samples examined was too small to enable a judgment to be formed of the purity of the food-supply or to have any deterrent effect upon the practice of adulteration. On the whole, however, the number of authorities who neglect to exercise their powers under the Act is becoming fewer every year. The net result of all this is that a slight increase in the percentage of adulteration over the previous year's returns is recorded. The total number of samples examined was 46,856, and of these 18,896 were samples of milk. Milk showed an adulteration of 10·4 per cent., while in the last official year the proportion of adulterated samples was 11·1 per cent. This is a slight though distinct improvement, which, moreover, occurred chiefly in the metropolitan returns. Five years ago 22·5 per cent. of the samples submitted for analysis in London were classed as adulterated. We may find in this, we think, distinct evidence of the fact of the power of the present Act to deal with offences so long as the authorities carry out the provisions with a due amount of vigilance. The report still records the imposition of small fines which are utterly incommensurate in most cases with the nature of the fraud or adulteration committed. There was, however, a slight increase in the amount of the average penalty imposed. In what particulars the Act requires revision is plainly evident from the statement that out of the 4383 samples reported by the analysts as adulterated prosecutions were instituted in respect of 2777 only. In one case, that of a sample of gin which had been sold at a strength of 4 degrees below the legal limit, the magistrate expressed the opinion that it was absurd to prosecute for so slight an offence and dismissed the case, ordering each side to pay its own costs. The authorities were thus placed in the perfectly absurd position of being fined for carrying out a statutory duty. Another point of importance in connexion with new legislation upon the subject is well brought out in the case of butter. The number of samples of butter

Digitized by Google

submitted to the analyst by private purchasers was 320 and of these as many as 175, or 54·7 per cent., were condemned. It is true that this enormously high return in regard to adulteration may be accounted for by the fact that only those samples which had aroused suspicion had been selected for analysis. Still, the results suggest an improved system of collecting samples for analysis. It should be added also that 34 per cent. of the general samples obtained by private purchasers were condemned. This figure is nearly four times the figure given as representing the extent of adulteration of samples obtained in the official manner. Further, there are probably many classes of offence which the operations of the present Act do not reach at all, and it is with these that a new Act will deal if it be based on the lines of the Bill introduced but dropped last session. Coming to drugs, the number taken for analysis is altogether inadequate and quite out of proportion to the number of samples of food. There were only 1964 examined and of these 10·5 were condemned.

THE METROPOLITAN WATER-SUPPLY.

The reports of Major-General Scott and of Sir Edward Frankland on the quantity and quality of the water-supply respectively are of especial interest at the present time in view of the critical state of affairs in the East-end of London, although, of course, they were written before the drought occurred. A comparison of the present reports with the reports of 1896 will show very little difference in their import. Indeed, many of the paragraphs are precisely the same, word for word. This probably accounts for an official blunder. Major-General Scott's report opens in the usual stereotyped way, and afterwards when he refers to Sir E. Frankland's report he says, as he said in exactly the same terms last year, that "at the request of the Associated Metropolitan Water Companies Sir E. Frankland has extended his monthly examinations to the chemical, physical, and bacterioscopic condition of the raw river water at the intakes of the several companies and to the bacteriology of the water as it issues from the filters of each company and before it is pumped into the distributing mains." Now, Sir Edward Frankland has not presented a bacteriological report at all in this year's statement of the work of the Local Government Board. We find absolutely no bacteriological data or references, and in the first paragraph of his report to Mr. Chaplin, Sir Edward Frankland simply states: "I have to report to you the results of the chemical analysis and of the physical examination of the water supplied by the eight metropolitan water companies and the Colne Valley Company during the year 1897." Putting aside any conjecture as to why a bacteriological examination was not conducted this year—or, at any rate, if it was it is not reported in the Blue-book—we are at a loss to understand why Major-General Scott points to a report which does not exist in official print. Sir Edward Frankland's report is again almost identical, word for word, with last year's report. The dates are of course different and some of the figures, but the interpretation is almost precisely the same, and last year's paragraphs have in a large measure served for the purposes of the present report. It will be remembered that two years ago the chemists to the London County Council reported that they had found suspended matter in the London water-supply which forced the conclusion that the filters were inoperative as regards removing the suspended matter peculiar to raw river-water. This evidently prompted Sir Edward Frankland in his report for 1896 to take up the question, and he stated among other things his opinion that the presence of the bacillus coli communis in water was no proof of sewage contamination because this organism is one of the most ubiquitous and persistent of harmless microbes. Then he added some remarks on the occurrence of suspended matter—remarks which are repeated in exactly the same terms in the report just issued. We reproduce the last sentences because a year ago we considered them in the light of a rejoinder to the London County Council's report two years ago and they were couched in similarly popular language:—"The amount of this suspended matter in the efficiently filtered river-water supplied to the metropolis rarely if ever exceeds 0·0002 grain in a tumblerful, and therefore in order to imbibe a single grain it would be necessary for the consumer to drink no less than 5000 tumblerfuls of the water. Such excessively minute quantities of matter which is presumably harmless may safely be neglected; indeed, it is impossible practically to obtain water free from it." We think that this and other continual reiteration is likely to cast discredit on official reports. The remarks of Major-General Scott as to his examination of the water supplied by the several companies and as to the condition and degree of efficiency of the works for its purification practically coincide with the points raised in the previous report of 1896. These turn largely on the daily discharge of the rivers and the relative quantity of water withdrawn, on the employment of cisterns, the extension of constant supply, the question of waste, and lastly on the desirability of securing a connexion between the mains of one company and those of another. "Such interconnexion of the mains of the several companies has been effected to some extent but not so fully as is desirable." This remark in particular occurs in the report of 1896 as well as in the one before us. According to Sir Edward Frankland the quality of the water-supply is free from reproach and here again practically the same remarks are made as to the points brought out in the series of analytical tables.

CHEMICAL TRADE NUISANCES.

The supervision exercised by the Local Government Board staff of special inspectors in regard to the working of the Alkali, &c., Works Regulation Acts continues to be attended by good results. The chief inspector states that reviewing the industry as a whole he has every reason to be satisfied with the care displayed and the competency of management shown and that complaints of damage to crops in the neighbourhood of works have almost ceased. The increased employment of electrolysis for the production of chlorine from common salt appears to be reducing very materially the risk of chlorine escaping in the air. One cause of nuisance to residents in the neighbourhood of chemical works appears to be the method of concentrating and rectifying sulphuric acid. There is a difficulty attending the suppression of this nuisance, but the matter has engaged, and is still engaging, the serious attention of the special officials appointed to see that the provisions of the Alkali Act are carried out.

THE OUTBREAK OF TYPHOID FEVER IN BELFAST.

THE monthly meeting of the city corporation of Belfast was held on Oct. 1st, and, as anticipated, there was an interesting discussion on the health of the city arising principally out of the reports of the Town Improvement and Public Health Committees. The report presented by the medical superintendent of health (Dr. Whitaker) for the period between August 21st and Sept. 17th was as follows: The number of cases of zymotic disease notified was 1121 cases of typhoid fever, 254 of simple continued fever, 46 of scarlet fever, 32 of erysipelas, 27 of diphtheria, 8 of membranous croup, 7 of puerperal fever, and 1 case of typhus fever. In the four weeks ending Sept. 17th there were 878 births and 673 deaths, a natural increase of 205. There were 234 deaths from zymotic disease, 81 from phthisis, and 83 from diseases of the respiratory organs, making a total of 164 from these two latter causes. In the corresponding period of 1897 the deaths from zymotic disease were 154. The annual death-rate from all causes was 28·8 and the mortality from zymotic diseases was 10·0 per 1000. While the number of cases of typhoid fever notified as well as the deaths from that disease are more numerous than in the preceding month, it is satisfactory to find that for the week ending Sept. 24th the number of cases notified was 164, or less than one-half that existed in the last week of August. The improvement in the health of Belfast in respect of typhoid fever appears in all the dispensary districts. The epidemic apparently reached its acute stage in the last week of August, and since then its diminution has been gradual until now it is less than one-half it was at the period referred to. The Public Health Committee in their defence claim that the epidemic has been put down by the measures adopted by them. They say they appointed a sub-committee on Sept. 1st and that the notifications of typhoid fever for the week preceding the assumption of their duties were 333, while in the week ended Sept. 24th the number was reduced to 124. The measures adopted by the Public Health Committee were (1) the employment of all the experienced officers of the Health Department; (2) the provision of vessels in houses where typhoid fever was present for the reception of dejecta, and their

Digitized by Google

subsequent removal and disinfection; (3) the more liberal flushing of the drains (through the kindness of the water commissioners) with water containing disinfectants in solution; and (4) the employment of Dr. Lorrain Smith to test water-supplies, milk-supplies, and to examine soil gathered from the infected areas, and to find out, if possible, the cause of the outbreak. His report has not been received. It is only fair, we think, to the Public Health Committee to state these facts; whether they are right or warranted in drawing the conclusion that by these means they have brought about a diminution in the cases of typhoid fever from 280 cases per week for the four weeks ended Sept. 17th to 164 for the week ended Sept. 24th is very doubtful. The impression of many people is that the improvement does not by any means indicate that the conclusion of an epidemic is being reached, but rather that the normal state of things in Belfast is being resumed, which unfortunately shows that, owing to the soil being laden with the germs of typhoid fever, due to past insanitary defects, the disease is always present—is, in fact, endemic; and that the so-called epidemic of typhoid fever in Belfast has been simply a recrudescence (due to the dry warm weather) of the normal condition of typhoid fever in Belfast, which is endemic. This is the problem the Public Health Committee have to face, and it is very pleasant to find that certain steps were decided on at the corporation meeting on Oct. 1st in this direction. For it was passed, "That a systematic test of all the drains of the city be made and that the head officers of the Public Health and Improvement Committees report what additional officers are necessary for this purpose and that such officers be appointed and a weekly return of the drains so tested be made to the above committees." A leading member of the Public Health Committee in moving this resolution confirmed what has been stated by the special sanitary commissioner of THE LANCET. He said that the Improvement Committee had in the past allowed drains to be constructed of the most imperfect character. In some cases ordinary field drains had been laid down for the purpose of carrying sewage away, and in one district with which he was formerly well acquainted large numbers of people were living in houses to which there were no drains whatever except into the street, where they terminated, there being no connexion between the street drain and the main drain. The Improvement Committee has up to the present neglected one of the provisions of the Public Health Act, which decreed that no house should be allowed to be inhabited until it had been examined and a certificate given as to its sanitary condition by the borough surveyor. The Public Health Committee were receiving the blame for the present insanitary state of the city and for the prevalence of typhoid fever in their midst, but they were in this position—the sins of their fathers who were the members of that corporation thirty years ago were being visited upon the present Public Health Committee and the corporation in general. He believed that the epidemic of typhoid fever was probably due to defective sewers and to the fact that the soil was saturated with filthy matter which had been there from time immemorial. The result, he said, of an examination of Belfast water negatived the idea that the epidemic was caused by the water. These opinions of a prominent member of the Public Health Committee corroborate fully the views put forward in THE LANCET as to the typhoid fever in Belfast being not merely epidemic but really endemic. Another most important project sanctioned on Oct. 1st was the erection of refuse destructors for getting rid of 200,000 tons of dry house refuse collected annually. Some of this has in the past been removed as farm manure; a good deal of it, it is said, has been used as the horrible material to "fill up" grounds in various parts of the city. A committee has been investigating this matter, and the corporation have sanctioned tenders being issued for the erection of refuse-destructor plant at an estimated cost of £10,000. It is arranged that this plant shall be erected at the pumping station output works of the city main sewage, and that the destructors shall provide sufficient power to work the pumping machinery and an electric plant for the lighting of the station. The work is to be begun at once.

It is regrettable to find that an attack was made by some members of the corporation on the medical profession in reference to the duplicating of returns under the Notification of Infectious Diseases Act, but the good sense of the great bulk of the corporation asserted itself on behalf of the medical men and the majority refused to allow the City Council to be made a vehicle for an attack on our profession. There may have been mistakes made by medical men notifying infectious diseases, due in many cases to the way the Act is framed, but the general results of notification have not been vitiated by such slips; and it should also be remembered that last winter when such charges of errors in notification were first made the Western Medical Society sent a circular to each of its members drawing their attention to what had been said. It is pleasant to be able to report that the city corporation of Belfast, aroused at last by a determined public opinion and the medical press have begun to grapple with the insanitary state of that city due to the sins of the past. Full credit must be given for the two most necessary reforms which they initiated last week, but they must go a great deal further, until typhoid fever ceases to be endemic in their midst, and until they have removed the reproach hurled so often at the inhabitants of a modern city that its death-rate from a preventable disease like typhoid fever is the highest in the United Kingdom.

OPENING OF THE MEDICAL SCHOOLS.

Guy's Hospital.—In accordance with the usual custom the session was opened by a meeting of the Physical Society. This was preceded by a house dinner in the college at which Mr. Charters J. Symonds took the chair in the absence of Dr. P. H. Pye-Smith, the president of the Students' Club. Sir Samuel Wilks, Bart., Mr. H. Cosmo O. Bonsor, M.P., and many members of the staff and students were also present. The large company afterwards adjourned to the new physiological theatre, where, after a short address of welcome to the new students from Sir Samuel Wilks, Mr. W. H. Crosse, F.R.G.S., late principal medical officer to the Royal Niger Company, read a paper on the Treatment of Malaria and Blackwater Fever.

King's College Medical School and Hospital.—The beginning of the medical session was, as usual of late years, marked by the annual dinner of the old students and their friends, who met at Limmer's Hotel on Monday, Oct. 3rd. The chair was occupied by Mr. A. Boyce Barrow, and he was supported by a very large gathering, which included almost all the members of the staff and many others who had travelled great distances in order to be present. In proposing the toast of "The Navy, Army, and Reserve Forces," Mr. Barrow alluded to the recent Egyptian campaign, and to the excellent work which had been done by King's men in the Royal Army Medical Corps. His allusions to Colonel A. T. Sloggett, who was seriously wounded at Omdurman, to Captain G. A. Bray, and to Captain H. E. H. Smith were received with enthusiasm. Colonel R. H. Jelf, C.B., and Captain H. L. Hughes responded to this toast. The toast of the evening, "King's College Hospital and its Medical School," was proposed by the Chairman and responded to by the Rev. Dr. Robertson, Principal of King's College and by Mr. C. Awdry, treasurer of the hospital. The toast of "The Chairman" was proposed by Mr. Richardson Cross, High Sheriff of Bristol, and it was greeted with musical honours. In the course of the evening Mr. Percy Webster and Mr. Herbert Schartau gave a selection of songs which was much appreciated. The proceedings were brought to an harmonious conclusion with the singing of "Auld Lang Syne."

Middlesex Hospital.—The annual dinner of the past and present students was held on Oct. 3rd at the Café Royal. The Right Hon. Sir Ralph Thompson, K.C.B., presided and the attendance was exceptionally large. After the usual loyal and patriotic toasts Sir Ralph Thompson proposed the "Middlesex Hospital and Medical School." A review of the past year, he said, showed that the hospital and school had steadily pursued a career of usefulness and prosperity. In the near future its sphere of usefulness would be still further increased by the addition of the new cancer wing. Dr. Cayley, in responding, spoke of the training of students and said that the desire was to send forth men into the world as thoroughly equipped as possible for their struggle with disease. Dr. Pasteur, the Dean, spoke of the great advance made by the new buildings which would make the school one of the best in the metropolis. Mr. T. W. Nunn proposed the "Past and Present Students,"

Digitized by Google

and alluded to the success which seemed to attend Middlesex men in every corner of the globe. Mr. E. A. Fardon, in replying for the past students, pointed out that both past and present were always united as students of disease. He alluded in feeling terms to the many who had passed away. Mr. C. G. Pugh replied for the present students. Mr. Stephen Paget proposed "The Visitors" and warmly thanked Mr. Wilhelm Ganz for his kindness in providing such a delightful programme of music and to this toast Mr. Ganz made an appropriate reply. Mr. Pearce Gould proposed the health of the chairman and dwelt on the skill and courtesy with which Sir Ralph Thompson always managed the affairs of the hospital and school. An excellent programme of music was provided during the evening under the direction of Mr. Wilhelm Ganz.

St. Bartholomew's Hospital.—The opening of the present session was inaugurated by the usual dinner of old students, which was held in the great hall of the hospital on Oct. 4th. Sir William Turner was in the chair and was supported by Sir Trevor Lawrence, the treasurer of the hospital, Sir H. F. Norbury, K.C.B., the Director-General of the Medical Department of the Royal Navy, and Surgeon-General Jameson, C.B., the Director-General of the Royal Army Medical Corps, Surgeon-General Hooper, Professor Ray Lankester, the Master of the Society of Apothecaries, Mr. Trimmer, Professor Arthur Thomson (Oxford), and Professor MacAlister (Cambridge). Of members of the staff there were present Dr. Church, Dr. Gee, Sir Dyce Duckworth, Dr. Brunton, Dr. Norman Moore, Dr. Herringham, Dr. Ormerod, Dr. Champneys, Dr. Griffith, Sir Thomas Smith, Mr. Willett, Mr. Langton, Mr. Marsh, Mr. Butlin, Mr. Walsham, Mr. Bruce Clarke, and Mr. Bowlby. Altogether there sat down 129. There were only five toasts and at the conclusion of dinner everyone adjourned to the library for coffee and smoking.

St. George's Hospital.—The annual dinner was held at the Whitehall Rooms, Hôtel Métropole, on Saturday evening, Oct. 1st. Mr. Holmes, treasurer of, and consulting surgeon to, the hospital, was in the chair. Covers were laid for 124 guests, a number which included past and present students and a few visitors. The meeting was an eminently successful one. The toasts proposed were the following: "The Queen and the Royal Family," "The Medical School," "The Governors of St. George's Hospital," "The Orator of the Day" (Mr. G. R. Turner), "Past and Present Students," and "The Chairman." Songs were sung during the evening by Dr. Llewellyn Powell and Mr. Trevor.

St. Mary's Hospital.—The annual dinner of the past and present students and of the athletic clubs was held at the King's Hall, Holborn Restaurant, on Oct. 3rd, Mr. J. N. Moore, J.P., being in the chair. Amongst the 211 present were Sir William Broadbent, Bart., Dr. Cheadle, Mr. Owen, Mr. George P. Field (Dean), Dr. Lees, Mr. Herbert Page, Dr. Sidney Phillips, Dr. Handfield-Jones, Mr. Juler, Mr. Anderson Critchett, Dr. Waller, F.R.S., Mr. H. G. Plimmer, Mr. Pepper, Lord Granville Gordon, Dr. Danford Thomas, Colonel Belemore, Colonel Myers, Mr. W. H. Cundell, Mr. J. R. Walker, Dr. Franklin Parsons, Dr. Caley, Dr. Scanes Spicer, Dr. Gow, Mr. H. S. Collier, and Dr. Luff (Sub-Dean). The toast of the "Queen and Royal Family" having been duly honoured on the proposal of the Chairman, that of the "Services" was proposed by Mr. Havell and responded to by Fleet-Surgeon T. J. Preston, R.N., Lieutenant-Colonel A. B. Myers, and Captain Whitcombe respectively. The Chairman then proposed "St. Mary's Hospital." Dr. Cheadle, senior physician, made a spirited speech in reply and proposed "The Dean" (Mr. G. P. Field), to whom so much of the success of the school was due. Mr. Field replied and proposed "Past and Present," responded to by Mr. Noble Smith and Mr. C. W. Buckley respectively. Mr. Edmund Owen, senior surgeon, then proposed "Athletics," to which Mr. J. E. Lane and Mr. A. G. Butler responded. "The Chairman" having been then proposed by Dr. Handfield-Jones the proceedings terminated with a short but enjoyable musical programme. A special feature of interest at the dinner was the presence of certain students specially invited by the School Committee as guests who had distinguished themselves during the past year in scholarship and athletics.

St. Thomas's Hospital.—The St. Thomas's Hospital Old Students' Annual Dinner took place on Oct. 3rd at the Whitehall Rooms of the Hôtel Métropole, Dr. Leonard W. Sedgwick being in the chair. The attendance was large and the dinner in every way was most successful. The chairman having proposed the toast of the "Queen and Royal Family," was followed by Sir William Mac Cormac, the President of the Royal College of Surgeons of England, who, in proposing the toast of "The Hospital and Medical School," gave some interesting reminiscences of the hospital as it was when he joined it twenty-five years ago. The treasurer, Mr. Wainwright, in response, commented on the thorough equipment of the hospital, and in thanking Sir William Mac Cormac for his appreciative remarks on the interest taken in the hospital by the Governors said that they had in view various schemes for still further improvement. Dr. Hawkins, the dean of the medical school, referred to the steadily increasing entries as an indication of the school's efficiency; the number of medals gained at London University and the very successful results at the College examinations also attested the same fact. He commented on the loss the hospital had sustained by Dr. Toller's appointment as physician to the hospital at Cairo. Mr. Mackellar also had resigned through ill-health. Dr. A. F. Stabb had been appointed assistant obstetric physician to St. George's Hospital. He also referred to the appointment of Dr. Perkins as fourth assistant physician. Dr. Bulstrode having spoken was followed by Dr. Crosby, who proposed the "Chairman." Dr. Sedgwick, in reply, spoke of the staff as it was when he joined the hospital fifty-three years ago, when Green, Grainger, and Marshall Hall were prominent figures. The toast of the "Secretaries" was proposed in a most amusing speech by the Rev. Dr. Merry and suitably responded to.

Westminster Hospital.—The annual dinner of the medical staff, members of the House Committee, past and present students of the school, and their friends was held on Oct. 3rd. The chair was taken by Sir George Scott Robertson, K.C.S.I., a former student and teacher in the school. A very pleasant evening was spent. After the usual loyal toasts those of the "Westminster Hospital Medical School," the "Old Students," the "Visitors," and the "Chairman" were duly honoured and replied to. Sir George Scott Robertson, in acknowledging the toast of his health, remarked that there was one thing which medical training did for a man. It taught him both to incur and face responsibility whenever it came upon him.

Medical Faculty of University College, London.—The annual dinner of the past and present students was held on Monday, Oct. 3rd, at the Hotel Cecil, Dr. Frederick Roberts being in the chair. About a hundred sat down. The chairman, in proposing the toast of the evening, "Success to University College and Hospital," referred to the many distinguished men who had been connected with the hospital, and mentioned that every London hospital, with the exception of Guy's, had an old University College student on its staff. Dr. Roberts, Dr. Beevor, and Dr. Philip Turner sang during the evening.

REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR THE YEAR 1896.[1]

SECOND NOTICE.[2]

THE most serious question which confronts the Government and the military authorities of India so far as the health of the European army is concerned is without doubt the great prevalence of venereal disease and of enteric fever in that country; the one gives rise to a large amount of present inefficiency followed by grave future consequences and the other to a long and severe illness and a very serious loss of life. While venereal diseases caused 37 per cent. of the total sickness enteric fever caused nearly 43 per cent. of the total deaths. As regards enteric fever the Sanitary Commissioner tells us that the differentiation of the bacillus and the treatment of the disease by enteric

[1] Annual Report of the Sanitary Commissioner with the Government of India, 1896, with Appendices and Returns of Sickness and Mortality among European Troops and Prisoners in India for the Year. Calcutta: Office of the Superintendent of Government Printing, India. 1898. Price, 5 rupees.

[2] The First Notice appeared in THE LANCET of Sept. 24th, 1898, p. 831.

Digitized by Google

serum, the diagnosis of the fever by the patient's serum-reaction to a true cultivation of the specific bacillus, preventive inoculation or vaccination, and the question as to how wide may be the dissemination of the enteric bacillus in nature continue to be the chief topics of interest. But first let us consider the prevalence of this disease in India. There were 1795 admissions from enteric fever with 445 deaths in 1896, against 1870 and 477 in the previous year, showing a slight decrease in the admission and death ratios per 1000 of strength in 1896. The average number of men constantly sick from enteric fever was 260, and the average duration of a case was 53 days (which does not of course show, however, that the men were fit for efficient service at the end of that time). The total loss to the service due to the disease was about 95,109 days. A table is given of the total fever mortality in the years 1895 and 1896 as compared with the two periods 1870–79 and 1881–90, which shows an increase of mortality from enteric fever and a decrease in mortality from other fevers in 1895 and 1896 as compared with the decennia.

These results are ascribed in the report under review, and probably quite rightly, to an increased susceptibility to enteric fever on the part of the army due to youth and recent arrival and partly to the increasing frequency with which the diagnosis of enteric fever has been made. Be the explanation what it may, however, a glance at the table shows that a progressively grave increase in the amount of fatal cases of enteric fever in India has been taking place. Turning to the section on the native army of India we find that the ratios for European troops in this respect are very unlike those for native troops and prisoners:—

	1886-95.		1896.	
	Admissions.	Deaths.	Admissions.	Deaths.
European troops ...	19·6	5·28	25·5	6·31
Native troops... ...	0·2	0·08	0·1	0·04
Jail population ...	0·3	0·12	0·2	0·06

It must be borne in mind that nearly every fatal case of disease in the jail population is subjected to post-mortem examination and, as has been so frequently pointed out in these reports, the fact that the ratios of prisoners and native soldiers are almost identical leaves little or no doubt on one subject—namely, that the amount of enteric fever among our European troops serving in India is altogether out of proportion to that in the native troops and the jail population. Moreover, the total fever mortality in the two armies—European and native—is not the same in amount, which is strongly corroborative of the view that the difference is real and not a mere matter of diagnosis. Among European troops enteric fever stands at 42·5 in the percentage of deaths from all causes, whereas among native troops it is represented by 0·4. It is frequently alleged that the natives of India nevertheless suffer from enteric fever to an unsuspected extent, but that they pay their tribute to that disease in infancy or early life and acquire immunity thereby from subsequent attacks. It may be so, but the assertion rests rather upon conjecture than upon any scientific basis or actual observation, for it has never been proved. It is possible, of course, that the continued exposure of the natives of India from earliest life upwards to the causes of enteric fever and an insanitary environment may tend to make them immune; that is also a plausible but unproved explanation. Still the fact remains that the relative insusceptibility of the native as compared with the European to enteric fever seems to be established, and we suspect that a difference of diet—the native's abstinence from meat and alcohol—may have some influence in this respect in a hot climate like that of the plains of India. Be this as it may, a great deal still remains to be done in the way of the scientific differentiation of the fevers of India. That typhoid fever largely prevails there cannot be doubted; the fever has all the clinical features, and when fatal all the special anatomical lesions, which characterise typhoid fever elsewhere. But there are some observers who are not yet convinced that every case of fever in India attended with ulcerative disease of the glands of the small intestine is absolutely identifiable with the typhoid fever of other climates and attributable to the same causes—the typhoid bacillus of Eberth and Gaffky, the life history and dissemination of which in nature has still to be thoroughly worked out. It is often urged, and undoubtedly with much force and justice, that soldiers do not get enteric fever in barracks, but in the native bazars and from the drinks they obtain there; but young officers do not commonly have recourse to native drinks or native bazars, and yet they are notoriously very liable to contract and to die from enteric fever. A great deal has been done of late to advance our knowledge of this fever, but the difficulties which have to be overcome in prosecuting our inquiries in India are both very numerous and great. The reports of the Sanitary Commissioner are calculated to do much good in this direction. Meanwhile enteric fever is a terrible scourge in India, which country we are compelled to be periodically supplying with a highly susceptible material in order to maintain the strength of the British Army serving there.

With regard to two fatal cases of enteric fever may be mentioned the existence of a single abscess of the liver in one case and of multiple abscesses in the other. The fact is somewhat interesting, because looking to the causal connexion between dysenteric ulceration and hepatic suppuration it has often been asked why abscess of the liver should not be more frequently seen in cases of typhoid fever. This brings us to the subject of hepatic abscess. Speaking generally, dysentery and hepatic abscess march together; groups of stations and districts which have a high admission rate from dysentery have also a high rate from abscess of the liver, but they are nevertheless not exactly conterminous with one another. The natives of India suffer very much from dysentery but rarely from hepatic abscess, nor is the latter disease a common sequence of dysentery in other countries where dysentery prevails. It is said that the Spanish troops in Manilla and Cuba suffered much from dysentery but not commonly from hepatic suppuration. Hepatic abscess is more frequently met with in the Madras than in the other presidencies of India. Of the cases of abscess of the liver in the army in India 34 per cent. were returned as having been associated with dysentery, or 52 cases out of 153. It used to be assumed that where an abscess of the liver was not associated with dysentery or a history of that disease the abscess was almost always single, whereas when hepatic suppuration was so associated that there were multiple abscesses. The bearing of this on prognosis is obvious, especially in the case of surgical operation being had recourse to; but the figures in the sanitary officer's report do not bear out this view. It cannot as a matter of fact be said that dysentery invariably or even commonly gives rise to multiple hepatic abscesses and not to a liver abscess.

THE SANITARY INSTITUTE: MEETING AT BIRMINGHAM.

(Concluded from page 896.)

Food Preservatives.

IN the section of Sanitary Science and Preventive Medicine Dr. ALFRED HILL, the President, dealt in his address with the question of food preservatives. In his opinion the use of chemical preservatives ought to be prohibited altogether. They enabled foods to be sold as fresh which were stale and which had undergone such putrefactive changes as to make them frequently harmful and sometimes actually poisonous. One of the difficulties in the way of putting down the use of preservatives was the different ways in which it was regarded by the justices in adjudicating on these cases. All additions to food the influence of which on health was doubtful ought to be prohibited and their use supplanted by refrigeration. A resolution was agreed to recommending the Sanitary Institute to present a memorial to the proper authorities calling attention to the recommendation of the Food Products Commission and urging that investigations by recognised scientific authorities into the effect of preservatives upon health be forthwith set on foot and that a court of reference be established.

The Birth-rate.

Dr. DAWSON WILLIAMS took for his subject "The Decline in the Birth-rate." He pointed out that when the census was taken in 1891 it was discovered that we had been making

Digitized by Google

an over-estimation of our population in England and Wales, and that whereas the estimate expected an increase since 1881 in round numbers of 3,750,000, the actual increase as ascertained by enumeration was only just over 3,000,000. The growth of a population was determined by the balance between births and deaths and the balance between immigration and emigration. The decline in our rate of growth had been due to a disturbance of both these factors. The births were 290,000 below expectation and emigration was 412,000 above expectation. The death-rate was lower, so that, in fact, the natural increase on balance of births and deaths ought to have been larger. He ascribed the diminished birth-rate to a progressive decrease in the number of children born to married English and Welsh women, and mentioned as a curious fact that the proportion of bachelors in a given number of males decreased steadily, not only during early adult life and maturity, but afterwards also. There were more infants born in towns than in the country in proportion to the population; but the infant mortality in the towns was so much higher than in the country that the town excess of births failed to maintain an excess in proportion to the total population.

The Progress of Sanitary Science.

Dr. G. SIMS WOODHEAD, President of the Physics, Chemistry, and Biology section, delivered an address in which he passed in review some of the more important advances which had been made in sanitary science in recent years. Twenty years ago, he said, tuberculosis was looked upon as a disease with which it was almost hopeless to contend with any great prospect of ultimate success—a conviction which was only now being gradually eradicated from the lay mind. With regard to diphtheria the outlook was equally gloomy up to five years ago. The spread of the knowledge of the laws of health amongst medical men, amongst corporate bodies, public societies, and individual laymen had, during the last few decades, done something to illumine a very great darkness, and tuberculosis and diphtheria were being systematically sapped and mined by most earnest workers.

The Pollution of Streams and Rivers.

Dr. CHRISTOPHER CHILDS said the evil of pollution had existed from time immemorial and it was admitted that the Rivers Pollution Act of 1876 had generally and persistently failed in the purpose for which it was intended. The chief difficulties in the way of the much-desired reforms were the ignorance and indifference of the people, the great cost of sewage purification, and the uncertainty with regard to the best means to be employed, the defects in the law itself, and the impotence of the measures provided for its administration. We could not, however, hope for thorough and effective legislation until the people had been roused from this indifference—until they were made fully conscious of the disgusting contamination to which their water-supplies were so commonly liable, until they were convinced of the consequent danger to which they were so constantly exposed, and until they insisted upon those reforms which would afford them reasonable protection.

Hospital Reform from a Sanitary Point of View.

Mr. T. GARRETT HORDER, honorary secretary of the Hospital Reform Association, read a paper on this subject, placing before his hearers the proposition that the aggregation of large numbers of sick people in the out-patient departments of our hospitals and infirmaries is detrimental to the well-being of the patients, is unnecessary, and is likely to cause the spread of infectious disorders. After describing the usual waiting-room of a large city hospital, in which men, women, and children suffering more or less from every conceivable disease congregate, mixed indiscriminately together, patiently waiting their turn to be called before the physicians and surgeons in attendance, he put the question, Can the waiting-room attendants be expected to distinguish between infectious and non-infectious cases? In the Clinical Hospital, Manchester, in 1895, Mr. Horder said, the following cases were treated in the out-patient department: measles, 8; whooping-cough, 9; chicken-pox, 6; enteric fever, 2; erysipelas, 2; pediculi, 40; and scabies, 50. In the Liverpool Infirmary for Children in 1896 the following cases were treated in the out-patient department: typhoid fever, 9; scarlet fever, 15; measles, 7; whooping-cough, 55; chicken-pox, 32; mumps, 17; diphtheria, 17; pediculi, 47; and scabies, 32. It might therefore be assumed that a similar condition of things occurs in the majority of the out-patient departments.

Infected Milk.

Dr. SCURFIELD (Sunderland) dealt with this question, remarking that it seemed very desirable that the Somerset House analytical authorities should adopt a higher standard for genuine milk, as there could be no doubt that the present low standard of 2·75 per cent. for fat and 8·5 per cent. for non-fatty solids allowed a large amount of adulteration to go on unchecked.

Tuberculous Meat.

Dr. JAMES NIVEN (Manchester) said that from careful inquiries which he had made he was able to show that the rule might be broadly laid down that healthy people did not contract phthisis except on prolonged and intimate exposure to sources of infection. The amount of meat actually containing tuberculous infective matter was, he believed, understated, but definite information could be obtained with regard to milk. A resolution was agreed to that all public institutions, hospitals, asylums, and public services ought to obtain milk from herds guaranteed free from tuberculosis by a competent veterinary surgeon, and that a Bill should be introduced at the earliest possible date for giving effect to the recommendations of the Commission.

The proceedings of the annual meeting were concluded with a popular lecture delivered by Dr. ALEX. HILL, Vice-Chancellor of Cambridge University, upon Unnatural Death. It was not the dangers of railway travelling or the few murders that occurred which brought down the average longevity of human life from 100 years to 50, he said. Something more subtle and murderous than that must be sought for. Every year 900,000 babies were born in England and Wales. If we took 1,000,000 children and saw what was likely to be the end of them we should find that 30,000 would die a violent death by accident, about 120,000 would succumb to the mysterious disease which we know now to be absolutely preventable—phthisis in its many forms—and only 45,000 would be allowed to live out their natural lives. One-quarter of all the diseases which destroyed life were absolutely preventable. If the practice of hygiene were only on a level with its theory the average longevity would be raised at once from fifty to sixty-five years. It was desirable that every citizen should have the same exact knowledge of the causes and properties of preventable diseases that the medical officer himself had.

"CONSCIENTIOUS OBJECTION" TO VACCINATION.—At the Cardiff Police-court on Sept. 24th a young man was granted a certificate of exemption on the ground of conscientious objection to the vaccination of his child. Dr. J. Mullin, who was one of the presiding magistrates, said that he took that opportunity of stating that they as magistrates had "conscientious objections" to the granting of these certificates. He added that the magistrates had a conscientious belief that the law permitted an act of gross injustice to the child, and they regarded the conscience clause as a great farce which would one day end in a tragedy and then they would hear no more about this conscience clause.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—A meeting of the Northern and Midland Division of this association will be held at the Derby County Asylum, Mickleover, near Derby, on Oct. 12th. A paper will be read by Dr. James Middlemass of the Sunderland Borough Asylum on the Treatment of Insanity by Thyroid Extract. An omnibus will leave the Midland Station, Derby, at 12 o'clock, reaching the asylum (five miles distant) in time for lunch, and Dr. Legge will provide lunch for members at 1 P.M. After the meeting members will be shown through the asylum by the medical officers. Dinner will be served at the Midland Hotel, Derby, at 8 P.M. Morning dress. Price 5s., exclusive of wines.—The autumn meeting of the South-western Division of this association will be held at the Grand Pump Room Hotel, Bath, on Wednesday, Oct. 19th, at 2.45 P.M. After the business meeting there will be a discussion on Dr. Blachford's paper read at the last meeting: Dr. Bristowe will read a paper on Lunacy in Private Practice; and Dr. Weatherly will contribute a paper on Lunacy and the Public. Dinner will be supplied at the Grand Pump Room Hotel at 5.30 for 6 P.M.

THE THOMPSON-YATES LABORATORIES OF PHYSIOLOGY AND PATHOLOGY IN UNIVERSITY COLLEGE, LIVERPOOL.

FIG. 1.

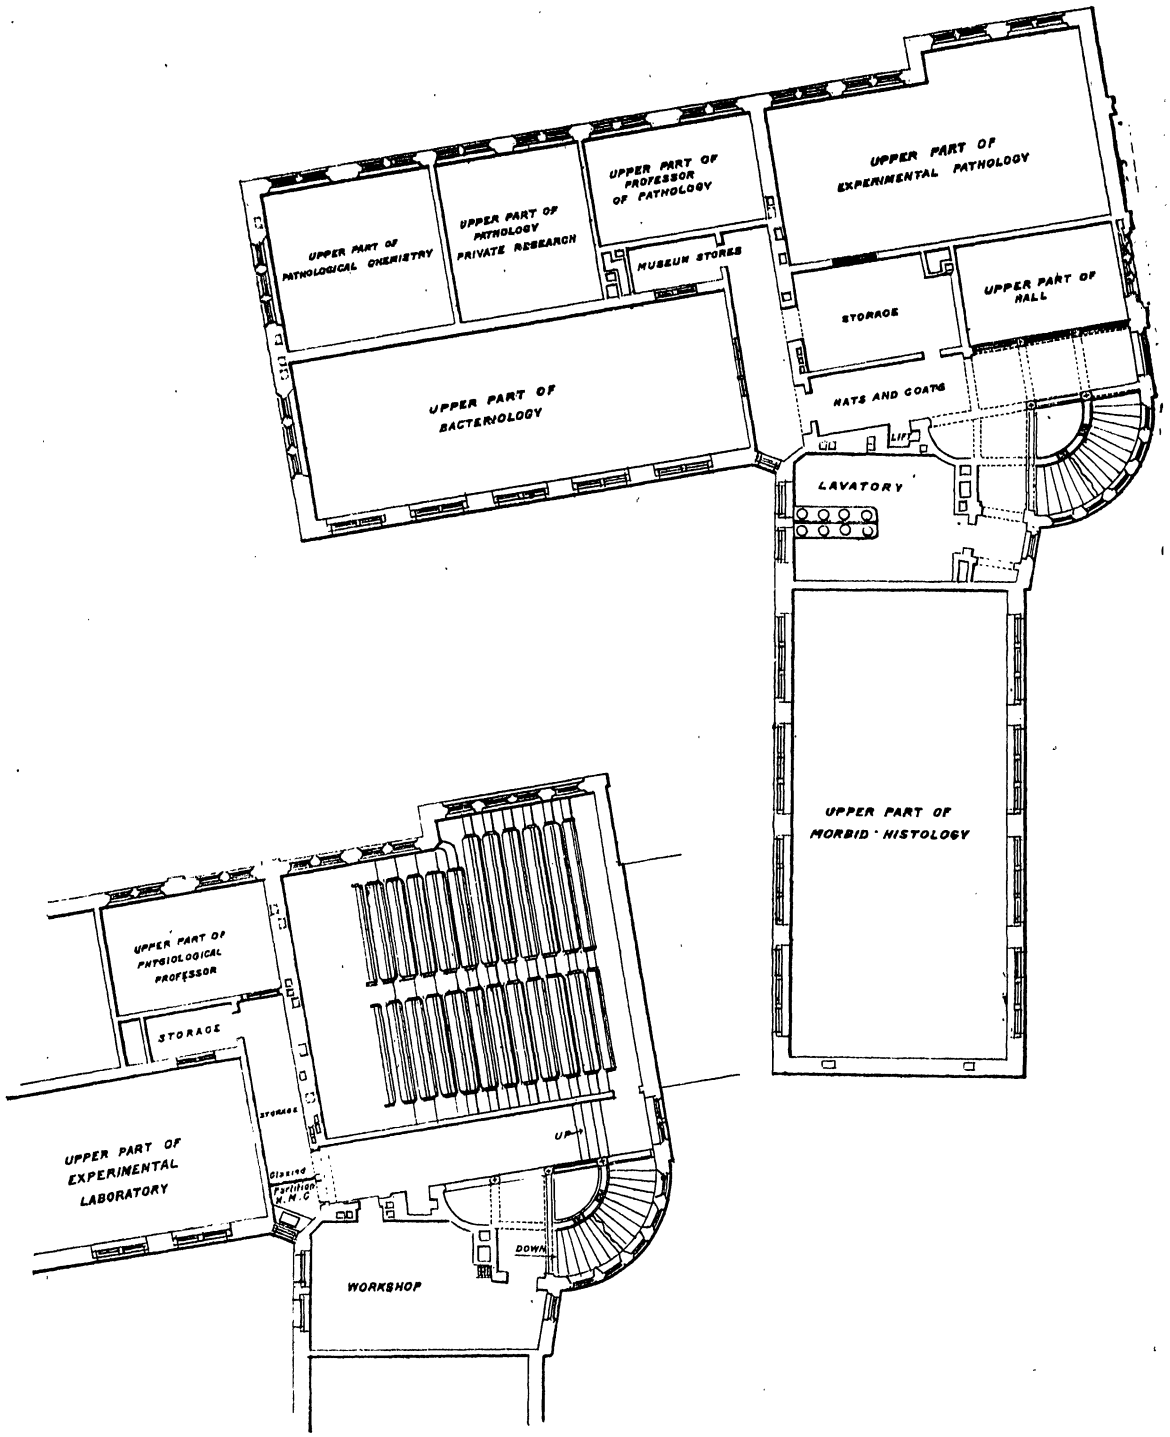

FIG. 2.

Fig. 1, plan of the floor between the ground and first floors; Fig. 2, plan of the floor between the first and second floors.

OUR Liverpool correspondent described last week at some length the noble gift which the Rev. S. A. Thompson-Yates has made to University College, Liverpool. We give above diagrams of two of the floor from which our readers can comprehend something of the completeness of the accommodation which is now offered to student and teacher alike in physiology and pathology at Liverpool. The laboratories will be opened to-day, Saturday, Oct. 8th, by Lord Lister.

COMPLIMENTARY DINNER TO PROFESSOR VIRCHOW.

A LARGE and representative gathering of members of the medical profession of Great Britain and Ireland assembled in the reception-room at the Hôtel Métropole on Wednesday, Oct. 5th, to receive their distinguished colleague, Professor Virchow. The following is a list of those present:—Lord Lister, who subsequently presided, Sir Samuel Wilks, Sir William Mac Cormac, Sir William Turner, Sir William Broadbent, Sir John Williams, Professor Chiene, Sir Henry Norbury, Surgeon-General Jameson, Sir Trevor Lawrence, Sir Henry Thompson, Sir William Roberts, Sir Thomas Smith, Dr. Hare, Mr. Timothy Holmes, Dr. Lionel Beale, Dr. Watt Black, Dr. Pavy, Dr. Saundby, Sir Douglas Powell, Sir William Gairdner, Sir William Gowers, Sir Dyce Duckworth, Sir Robert Craven, Mr. Hutchinson, Dr. W. H. Dickinson, Dr. Robert Barnes, Dr. Bastian, Dr. Herman Weber, Dr. Lauder Brunton, Dr. Sansom, Dr. Crookshank, Dr. Althaus, Dr. Dawson Williams, Dr. Luff, Professor Kanthack, Mr. D'Arcy Power, Dr. Holman, Mr. Shirley Murphy, Dr. Glover, Dr. Coupland, Dr. Buzzard, Mr. Watson Cheyne, Mr. Malcolm Morris, Mr. Brudenell Carter, Dr. Ferrier, Dr. Poore, Dr. Radcliffe Crocker, Dr. Sims Woodhead, Mr. T. W. Nunn, Mr. Macready, Mr. Noble Smith, Dr. Ferguson, Dr. Meek, Dr. Dupont, Dr. Leeson, Dr. Allison, Dr. H. Williams, Dr. R. Jones, Dr. Abraham, Dr. Percy Smith, Dr. Dakin, Dr. Newton Pitt, Major McLaughlin, R.A.M.C., Dr. A. Jamison, Dr. E. H. Williams, Mr. Robert Jones, Mr. Ernest Clarke, Dr. L. M. Griffiths, Dr. P. Horrocks, Dr. Galloway, Dr. W. Hill, Mr. Ernest Lane, Mr. Howard Marsh, Mr. Cowell, Dr. Ewart, Dr. John Anderson, Dr. Habershon, Mr. James Berry, Mr. Swinford Edwards, Mr. M. Ling, Dr. Scanes Spicer, Dr. Haydn Brown, Mr. Work Dodd, Mr. H. J. Curtis, Dr. Wynter, Mr. W. T. Lister, Mr. Spokes, Dr. A. G. Phear, Dr. Hunter, Dr. G. F. Blacker, Mr. L. Cheatle, Dr. V. Harris, Mr. R. Johnson, Dr. Washbourn, Dr. G. Murray, Mr. H. G. Plimmer, Dr. C. J. Arkle, Dr. Bradford, Professor Ray Lankester, Mr. Owen Lankester, Mr. Bowlby, Mr. Fripp, Dr. James Taylor, Mr. Walsham, Dr. S. West, Dr. Sainsbury, Mr. G. Barling, Mr. B. Pollard, Dr. Mott, Dr. Spencer, Dr. Pye-Smith, Mr. W. Anderson, Dr. T. Williams, Dr. G. Fletcher, Mr. Crichett, Mr. Field, Dr. Ogilvie, Dr. Briscoe, Dr. R. W. Burnet, Dr. Chapman, Dr. Nix, Dr. Slimon, Mr. Andrew Clark, Mr. Pickering Pick, Mr. Willett, Dr. E. Seaton, Dr. Caton, Mr. R. Harrison, Dr. Bowles, Mr. Butlin, Dr. Goodhart, Dr. S. Mackenzie, Mr. Page, Mr. Tweedy, Dr. F. T. Roberts, Dr. Oliver, Dr. Allchin, Professor Corfield, Mr. W. H. Bennett, Surgeon-General Hooper, Dr. Biss, Dr. Gibbons, Dr. E. H. Hare, Dr. Abercrombie, Mr. Adams Frost, Mr. Gould, Mr. G. H. Makins, Dr. T. H. Green, Dr. Dreschfeld, Dr. Payne, Dr. Charlewood Turner, Dr. Haviland Hall, Dr. Sharkey, Mr. Barker, Mr. H. P. Symonds, Sir Hugh Beevor, Dr. W. R. Smith, Dr. Shingleton Smith, Dr. McCall Anderson, Dr. Whipham, Dr. Champneys, Dr. Eastes, Dr. Charters Symonds, Sir Felix Semon, Dr. Church, Mr. Croft, Mr. Langton, Dr. Eustace Smith, Mr. Howse, Dr. Gee, Mr. Alfred Cooper, Mr. C. Stonham, Dr. Owen Fowler, Dr. Voelcker, Dr. Penrose, Mr. J. H. Morgan, Mr. W. Braine, Mr. Michels, Dr. Chavasse, Mr. Freyer, Dr. O'Brien, Mr. Mirhead Little, Dr. Kingston Fowler, Mr. Waterhouse, Dr. Brockman, Mr. Bidwell, Mr. H. B. Robinson, Dr. Griffiths, Mr. Arbuthnot Lane, Mr. F. Durham, Dr. Perry, Dr. Herringham, Dr. C. Beale, Mr. J. Griffiths, Dr. T. R. Cross, Mr. Storer Bennett, Mr. B. Roth, Dr. Angell, Dr. W. A. Davies, Dr. T. Duka, Dr. C. Godson, Mr. Nettleship, Dr. Cheadle, Mr. Clutton, Dr. Acland, Dr. Leech, Dr. Mitchell Bruce, Mr. Godlee, Mr. S. Boyd, Dr. Pasteur, Dr. Beevor, Dr. V. Voss, and Dr. Montague Murray.

During the evening an anonymous telegram was handed to Professor Virchow, containing the following words: "Get thee hence, vile vivisector! England spurns thee!"

The toast of "The Queen" having been duly honoured,

Sir WILLIAM BROADBENT proposed the toast of "The Naval and Military Medical Services." The wording of this toast, he said, showed an important deviation from the toast recorded on the toast list. It was the first time that the medical departments of the two Services had been recognised by a special toast. Even at medical dinners the toast had usually been "The Navy and the Army," and the medical departments had been dragged in apologetically. He was glad to see a departure from this custom because the medical departments of the two great Services were well worthy of a special toast when the dinners were so pre-eminently, if not exclusively, medical. As medical men they were proud of the medical departments of the Navy and the Army, and he thought the prominence given to this toast was propitious. There was a growing recognition of the importance of the medical services in the conduct of campaigns. Campaigns had been ruined for want of medical knowledge and professional skill, but in our latest campaigns—in central Africa, in the wilds of Afghanistan, and more particularly in the last brilliant campaign—the medical department had shone conspicuously. The medical department of the navy was universally recognised as efficient, and a department which had given to the profession and to the world such men as Darwin and Huxley was well worthy of every recognition.

Sir HENRY NORBURY, Director-General of the Medical Department of the Royal Navy, in responding, said the navy as it existed to-day was never in a more efficient condition. He referred to the work which had been done by the blue-jackets in recent engagements and concluded by remarking that the navy was worthy of the greatest confidence of the country.

Surgeon-General JAMESON, Director-General of the Army Medical Staff, in responding, said that it had been frequently said of late that the responsibilities of Her Majesty's army were ever increasing, and he could positively state that the responsibilities as far as his department was concerned were increasing in corresponding degree. Responsibility begot experience, and often we got experience through our own misfortunes and the misfortunes of others. Our good friends the Americans had just afforded us an object-lesson of how to improvise an efficient medical service from outside material. He did not assert that the task was impossible, because the Americans had performed it before. They succeeded in that task during the great War of Secession, but they did so after an expenditure of life and money unparalleled in the history of the world and after four years of bitter experience. Our estimates were framed on the assumption that success in battle was a certainty; but war was full of strange chances and the unexpected often happened. The work of the medical department during the late frontier war in India and Egypt was exceedingly good and in the case of the war on the Indian frontier there was not a case of septic disease from beginning to end. He need hardly state at that gathering that that result had been obtained only by following the principles laid down by the chairman, Lord Lister.

Lord LISTER, who read communcations of regret for unavoidable absence from Sir John Simon, Sir James Paget, and Sir Thomas Grainger Stewart, proposed the toast: "The Health of our Honoured and Beloved Master, Professor Virchow." Many of those present, he said, had had the advantage of his personal instruction; all might rank as his disciples, for the truths which he has enunciated have been studied and learnt by us all. Comparatively few in the present company recollected the effect which was produced by the first production of his *Cellularpathologie*, which swept away the false and barren theory of structureless *blastema* and established the doctrine that every morbid structure consists of cells which have been derived from pre-existing cells as a progeny. No part of the great discourse which they had heard two days ago was of deeper interest than Professor Virchow's observations which led him into the true path. Cellular pathology was now universally recognised as a truth. One portion of Virchow's doctrine had, indeed, required some modification—that portion in which he ascribes suppuration to proliferation of cellular elements. Certain collections, which we must admit to be of pus, were now known to be the result of the migration of leucocytes; but that all suppuration is produced in that way he did not himself believe. From his own investigations he came to the conclusion that there was a great deal more truth in Virchow's original view than has been generally assumed. Another kind of cellular pathology had come into existence in comparatively recent years—that abnormal conditions of tissues and functions were very often induced by the actions of parasitic cells, whether vegetable or animal, introduced from without. Those who heard the Huxley Lecture two days ago would know that Professor Virchow was thoroughly

Digitized by Google

alive to the progress of this new cellular parasitic pathology. In pathology Professor Virchow reigned supreme, but there were various other departments of human activity which he had made his own. No man was better versed in the history of medicine. He was an acknowledged authority in anthropology, a distinguished antiquarian, and a great politician. He did much to ameliorate the governmental conditions of his own country and later on in life his activity in the Reichsrath was so powerful that he became leader of the Opposition. One thing must be admitted by all—that Virchow's voice was ever heard in defence of liberty, truth, and righteousness. Lord Lister concluded by dwelling upon the large-hearted benevolence of Professor Virchow and his amiable character, which made him always ready to recognise work done by others, whosoever they might be. The toast was honoured with great enthusiasm.

Professor VIRCHOW responding said: The most kind and flattering words of your chairman have much surpassed not only my expectations, but my merits. I was prepared to find a friendly reception in your country, in which I have so often been hospitably received and where I always feel at home. I am no stranger amongst you. You all know that I have always been a friend of England. Even long before I had had the privilege of friendly relations with many of its best sons I had learned to admire the country and the people which, steadfast amongst the storms of the political movements of Europe, has preserved and developed the principles of civil and religious liberty—a glorious example for the whole of mankind. My inclination towards historical studies had made me familiar with the long roll of clever and successful investigators who had opened up to an unexpected degree the knowledge of nature in general and more particularly the knowledge of the nature and the internal processes of man. With respect and admiration I gazed at the work perfected by so many leading spirits. And then it was that I learned with delight how generously this people appreciates the work of foreign science, and how solid and lasting is the friendship accorded to those whom it considers to be its friends. Thus I have gladly accepted the invitation which has called me here now, and thus I feel again as if I were at home. Again I am under the hospitable roof of my old friend and pupil, Sir Felix Semon, who has so often been my guide and *fidus Achates* amongst you. Thus I see again the large number of distinguished men who are never tired of showing me that they are fond of me. Above all I wish to return my heartiest thanks to my venerable friend Sir James Paget, whom neither age nor infirmity prevented from calling on me. I salute with genuine emotion Lord Lister, whose immortal claims to glory outshine even his exalted position. I see around me the representatives and members of the oldest and greatest medical corporations of Great Britain, from whose works I have derived much instruction, much instigation to further labours. To-day, I think, I may say how much I have been touched by the confidence you have placed in me in choosing me to renew the remembrance of the great investigator whose commemoration we have just been celebrating. My task the other day demanded that I should demonstrate Huxley's influence upon the development of mental science. To-day I wish to emphasise that his merits in anthropological and ethnological respects are so great in the eyes of German *savants* that they alone would suffice to procure immortal reverence for his name. We shall not cease to follow in his footsteps and to defend the place which he has assigned to man in nature. Together with you we will try to clear up in every direction the biological history of man. May this task still further confirm and strengthen the solid union of English and German science. May the corporations of Great Britain and Ireland, which form the bulwark of medical science and practice that has remained unshaken for centuries, continue to give the world by teaching and example a guarantee that the results of our science may benefit mankind in an ever increasing degree. Before I sit down I ask you to drink with me to "The Health and the Prosperity of the Medical Corporations of Great Britain and Ireland," coupling with that toast the names of the Presidents of the Royal Colleges of Physicians and Surgeons, my old friends Sir Samuel Wilks and Sir William Mac Cormac, as well as of that distinguished representative of Scotch science Professor Chiene, the President of the Royal College of Surgeons of Edinburgh.

Sir SAMUEL WILKS, President of the Royal College of Physicians of London, said he claimed for the college which he represented a relationship with Professor Virchow, a distinguished Fellow of their body, the late Dr. Chance, having been the translator of the first English edition of Professor Virchow's chief work. Their guest belonged to no nation, time, or age. Pathology made the whole world kin. When English pathologists met men like Professor Virchow they felt that they were in sympathy with him, that their brains as it were were attuned to the same string. He remembered the time, now somewhere about forty years ago, when he was beginning to study the subjects which Professor Virchow had so advantageously taken up. He and his contemporaries were groping their way in the dark, when a light came upon them suddenly from afar—a light which illuminated everything and penetrated into the interior and gave them a new insight into physiology and pathology. Professor Virchow came to generalise like another Newton and gave them the *Principia* of medical science. If he might change the names he might say with Pope:—

> "Nature and Nature's laws lay hid in night:
> God said 'Let Virchow be!' and all was light."

Sir WILLIAM MAC CORMAC, President of the Royal College of Surgeons of England, said he was sure that everyone desired to do honour to such a man as their honoured guest and that he trusted that Professor Virchow would take back to his own country the belief that nothing which it was in their power to offer him was wanting. In Professor Virchow there was only one thing greater than the position which he held, and that was his modesty and his kindness.

Professor CHIENE, President of the Royal College of Surgeons of Edinburgh, who also responded to the toast, said that science knew no boundary, it recognised no nationality; its sphere was the universe, its object the good of humanity. In honouring Professor Virchow they were also honouring themselves.

Sir WILLIAM TURNER, President of the General Medical Council, proposed "The Health of the Chairman," and Lord LISTER briefly acknowledged the toast, concluding by handing Professor Virchow a book containing the names of all those present.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6652 births and 4695 deaths were registered during the week ending Oct. 1st. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 24·6 to 23·6 per 1000, further fell last week to 21·8. In London the rate was 19·7 per 1000, while it averaged 23·3 in the thirty-two provincial towns. The lowest rates in these towns were 13·8 in Croydon, 15·5 in Cardiff, 16·4 in West Ham, and 16·5 in Leicester; the highest rates were 28·8 in Hull, 32·3 in Sunderland, 33·7 in Gateshead, and 35·5 in Salford. The 4695 deaths in the thirty-three towns last week included 1119 which were referred to the principal zymotic diseases, against 1546 and 1455 in the two preceding weeks; of these, 884 resulted from diarrhœa, 66 from whooping-cough, 60 from diphtheria, 53 from "fever" (principally enteric), 30 from measles, and 26 from scarlet fever. The lowest death-rates from these diseases were recorded in Croydon, Leicester, Halifax, and Birkenhead; and the highest rates in Norwich, Salford, Hull, and Gateshead. The greatest mortality from measles occurred in Norwich; from scarlet fever in Salford; from whooping-cough in Gateshead; from "fever" in Huddersfield, Bolton, and Birkenhead; and from diarrhœa in Norwich, Manchester, Salford, Hull, Sunderland, and Gateshead. The 60 deaths from diphtheria in the thirty-three towns included 33 in London, 6 in Swansea, 5 in Leeds, 3 in Birmingham, and 3 in Liverpool. No fatal case of small-pox was registered during the week under notice in any of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals on Saturday last (Oct. 1st). The number of scarlet fever patients in these hospitals and in the London Fever Hospital on the same date was 2459, against 2300, 2319, and 2353 at the end of the three preceding weeks; 300 new cases were admitted during the week, against 273, 243, and 288 in the

Digitized by Google

three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 135 and 157 in the two preceding weeks, further rose last week to 200, and were slightly above the corrected average. The causes of 48, or 1·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bolton, Oldham, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·8 and 19·7 per 1000 in the two preceding weeks, declined again to 19·1 during the week ending Oct. 1st, and was 2·7 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·7 in Leith and 17·6 in Glasgow to 25·5 in Greenock and 28·2 in Paisley. The 577 deaths in these towns included 75 which were referred to diarrhœa, 17 to whooping-cough, 14 to "fever," 11 to scarlet fever, 6 to measles, and 4 to diphtheria. In all, 127 deaths resulted from these principal zymotic diseases against 157 and 156 in the two preceding weeks. These 127 deaths were equal to an annual rate of 4·2 per 1000, which was 1·0 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 110 and 104 in the two preceding weeks, further declined to 75 last week, of which 32 occurred in Glasgow, 14 in Edinburgh, and 14 in Dundee. The 17 deaths from whooping-cough showed a decline of 5 from the number in the preceding week, and included 10 in Glasgow, and 4 in Edinburgh. The deaths referred to different forms of "fever" which had been 9 and 13 in the two preceding weeks, further rose to 14 last week, of which 6 occurred in Glasgow, and 5 in Paisley. The 11 fatal cases of scarlet fever also showed a further increase upon recent weekly numbers, and included 6 in Glasgow and 3 in Aberdeen. Of the 4 deaths from diphtheria 3 occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 68 and 85 in the two preceding weeks, further rose to 87 last week, but were 50 below the number in the corresponding period of last year. The causes of 36, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 30·7 to 27·0 per 1000, further fell to 24·6 during the week ending Oct. 1st. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 24·3 per 1000, the rate during the same period being 19·4 in London and 18·7 in Edinburgh. The 165 deaths registered in Dublin during the week under notice showed a decline of 16 from the number in the preceding week, and included 38 which were referred to the principal zymotic diseases, against 35 and 32 in the two preceding weeks; of these, 27 resulted from diarrhœa, 5 from whooping-cough, 5 from "fever," (principally enteric), 1 from scarlet-fever, and not one either from small-pox, measles, or diphtheria. These 38 deaths were equal to an annual rate of 5·7 per 1000, the zymotic death-rate during the same period being 3·9 both in London and in Edinburgh. The fatal cases of diarrhœa, which had declined from 38 to 20 in the three preceding weeks, rose again to 27 last week. The deaths referred to different forms of "fever," which had been 3 and 6 in the two preceding weeks, were 5 last week. The fatal cases of whooping-cough, which had been 4 in each of the two preceding weeks, rose again to 5 last week. The 165 deaths registered in Dublin last week included 42 of infants under one year of age, and 39 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons exceeded the number recorded in the preceding week. Four inquest cases and 5 deaths from violence were registered; and 44, or more than a fourth, of the deaths occurred in public institutions. The causes of 13, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced: — Staff Surgeon Ernest E. Bray to the *Dido*. Surgeon Shirley H. Birt to the *Icarus*, additional.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Captain Green, Officiating Civil Surgeon of Howrah, are placed temporarily at the disposal of the Chairman of the Corporation of Calcutta. This cancels the notification placing the services of Captain Deare at the disposal of the Chairman. Captain Brown, Civil Surgeon of Purnea is appointed to act as Civil Surgeon of Howrah, during the absence on deputation of Lieutenant-Colonel Murray until further orders. Captain Vaughan, Deputy Sanitary Commissioner, Western Bengal Circle, is appointed to act as Civil Surgeon of Burdwan, during the absence on leave of Lieutenant-Colonel Gregg until further orders. Major J. Shearer, D.S.O., Bengal Establishment, 27th (Punjab) Regiment of Bengal Infantry, to be Secretary to the Principal Medical Officer, Her Majesty's Forces in India, *pro tem.*, vice Lieutenant-Colonel C. H. Beatson, whose tenure of appointment has expired. Major Moscardi Bellarmin Braganza (Bombay), 30th Regiment of Bombay Infantry (3rd Baluch Battalion), retires from the service.

VOLUNTEER CORPS.

Rifle: 1st (City of Bristol) Volunteer Battalion the Gloucestershire Regiment: Surgeon-Lieutenant J. Young to be Surgeon-Captain.

NATIONAL SOCIETY FOR AID TO THE SICK AND WOUNDED IN WAR.

The following is a letter dated from ss. *Mayflower*, Cairo, Sept. 18th, 1898, and addressed to the above society by Major W. A. Cowen, R.A.M.C.: "I beg to submit the following report *re* the trip of the National Aid Society's steamer *Mayflower* for the conveyance of sick and wounded from Assouan to Cairo. On Sept. 6th I took over medical charge of the ship, having under my command one medical officer, one serjeant, one corporal, and six privates of the Royal Army Medical Corps. The medical and surgical equipment was supplied from the military hospital at Cairo and proved adequate for the purpose. Three civil nurses were sent out from London by the society; they gave great satisfaction and were zealous in the performance of their duties. The sick and wounded received military rations for the journey, which were supplemented with the society's stores or substituted where necessary. The ship had accommodation for 52 men; double-berthed cabins on the upper deck to accommodate 30. On the lower deck the arrangement of the cabins has been altered, the partitions between the cabins being taken away and the berths arranged in two tiers, 12 on the starboard and 10 on the port side. This proved of great convenience, as it enabled stretchers to be taken inside the cabin and right up to the berth's side. All cases confined to bed, such as wounds of the leg and dysentery, were treated, as far as accommodation permitted, on the lower deck. Assouan was reached midday, Sept. 13th. At 10 A.M. on the 15th a sick convoy, consisting of 6 officers and 44 men, arrived by train from Shellal. The embarkment took place at once and within an hour the ship left for Cairo. Of the 6 officers 4 were wounded, 3 by bullets, 1 by a sword, while 2 were suffering from dysentery. Of the 44 men, 27 were wounded and 17 had dysentery and fever. The wounds consisted of bullet, sword, and spear, some of the men being wounded in two and three places. The great feature in the ship, in my opinion, is that wounds could be kept at physiological rest, this being conducive to treatment and comfort not to be obtained in a railway journey. Then, again, wounds could be, and were, dressed daily on strictly antiseptic principles, thereby minimising considerably deleterious after-effects. In conclusion, I beg to express the surprise and delight of both officers and men at the ship and its comforts provided for them, and which I feel sure will be most gratifying to the society. The ship arrived at Cairo on the afternoon of Sept. 18th, when the sick and wounded were conveyed by ambulance to the hospital." The following telegram has been received: "Society's hospital steamer *Mayflower* reached Cairo on Saturday evening, Oct. 1st, with the last of the wounded

Digitized by Google

from the battle of Omdurman—namely, 3 officers (Brinton, Nesham, and Nicholson), and 44 men; also 2 officers (Graham and Archer) and 2 men, sick, all benefited by the care bestowed upon them while on the steamer, which left on Sunday (Oct. 2nd) for Assouan to bring back the remainder of the sick from the front."

SURGEON-GENERAL CLEGHORN, C.S.I., I.M.S.

Although no official intimation had reached India up to the date of the reception of the last mail from that country it seems certain that Surgeon-General J. Cleghorn, M.D. St. And., C.S.I., the Director-General of the Indian Medical Service and Sanitary Commissioner with the Government of India, has announced his intention of retiring at the end of his furlough in this country. Surgeon-General Cleghorn, who has just been appointed honorary surgeon to the Queen, vice Deputy Surgeon-General S. B. Partridge, C.I.E., deceased, has had a long and distinguished career in India, where he will be much missed. He held the post of civil surgeon at Lucknow for a long time and, it will be remembered, was the delegate appointed to represent the Indian Empire at the Sanitary Convention at Geneva, where he did excellent service in connexion with the outbreak of plague in India. Surgeon-General R. Harvey, who has been filling the post of Director-General of the Indian Medical Service, and that of Sanitary Commissioner with the Government of India during the absence of Surgeon-General Cleghorn, will, no doubt, be confirmed in the appointment, and, from all that is known of him and of his eminent and varied services, he should prove a worthy and competent successor to and occupant of the post. Surgeon-General Churchill, R.A.M.C., officiating principal medical officer, Bengal command, has proceeded to England on three months' leave, Colonel Price, R.A.M.C., meanwhile officiating in his stead. It is understood that Surgeon-General Catherwood, R.A.M.C., now serving in this country, will be nominated to the post of principal medical officer of the Bengal command.

THE NILE EXPEDITION AND THE ROYAL ARMY MEDICAL CORPS.

A despatch has been received by the Secretary of State for War from the General Officer Commanding the Force in Egypt, Sir H. Kitchener, K.C.B. The following officers of the Royal Army Medical Corps are specially mentioned in the despatch: Lieutenant-Colonel A. T. Sloggett (wounded), Lieutenant-Colonel G. A. Hughes, Major C. A. Webb, Major G. Robinson, Major G. F. A. Smythe, Major D. Wardrop, Major R. W. Barnes, Major E. M. Wilson, Major A. Dodd, Major M. O'D. Braddell, Major C. R. Kilkelly, Major W. H. Pinches, Major H. M. Adamson, Major D. M. O'Callaghan, Major H. B. Mathias, Captain A. Y. Reily, Captain R. H. Penton, Captain H. E. Hill Smith, Captain C. S. Spong, Captain P. H. Whiston, Captain G. A. T. Bray, Captain J. W. Jennings, Captain H. N. Dunn, Lieutenant E. W. Bliss, and Lieutenant S. L. Cummins. In reference to Lieutenant-Colonel Sloggett an amusing story was related by Surgeon-General Jameson at the dinner to Professor Virchow on Wednesday evening last. Lieutenant-Colonel Sloggett was shot at Sir H. Kitchener's great battle, the bullet entering immediately above the left nipple. The ordinary aseptic dressing was applied and the wound healed in three days. When he reported himself to the Director-General in London, Surgeon-General Jameson asked him how it was that the bullet did not enter his heart, and remarked that Lieutenant-Colonel Sloggett ought to apologise for being alive. The latter replied that he thought his miraculous escape must be accounted for by the fact that his heart was in his boots at the time!

THE LATE SOUDAN CAMPAIGN.

The Sirdar evidently agrees with Marshal Saxe that an army marches on its belly, for he specially alludes in his late despatch to the excellent way in which the soldiers composing his force were rationed in the field and to the favourable effect this had in fortifying their health and strength. If an army is well fed and looked after, suitably clad and not habitually overworked, it is generally healthy, although it cannot, when the excitement of the struggle is over, be expected to escape altogether the sickness incidental to campaigning in a hot climate. As so frequently happens, no sooner is the nervous exertion and strain over than the troops begin to manifest and harvest the sickness they have contracted during active operations in the field. The latest advices from Cairo, however, state that the health of the troops has been much better than was expected. The death-rate from dysentery and enteric fever is lower than it was after the Dongola campaign.

THE MEDITERRANEAN SQUADRON.

We see by the papers that some dissatisfaction has been caused among naval medical officers serving with the Mediterranean fleet at the promulgation of an order that every ship is to have a surgeon on board at all hours of the day. We do not know, of course, what reasons the admiral may have had for this order, although he is quite within his power and rights to enforce it. The custom has hitherto been, where several ships were together, for a certain proportion of medical officers to remain on board their ships after working hours so as to be at once available if and when required. So far as we know this has hitherto worked very well. A rigid enforcement of the order that every ship is to have a medical officer always on board would practically make a prisoner of the medical officer where there happened to be only one on board a small ship; but there is probably some explanation forthcoming.

MAJOR MARCHAND'S MISSION.

It seems that Major Marchand's command at Fashoda is to be reinforced. At all events, the gallant adventurer is to have the services of another medical officer in addition to the Dr. Emily whose special promotion was recently mentioned in this column,[1] and doubtless the new candidate for Soudan distinction will not travel without an escort. According to a Ministerial order dated August 23rd, 1898, Dr. Ascornet, naval surgeon of the second class, has been struck off the strength of a marine battalion at Toulon in order that he might be "attached to the Marchand mission."

THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The winter work of the school commenced on Monday, Oct. 3rd, when two large classes paraded for instruction under Brigade-Surgeon-Lieutenant-Colonel P. B. Giles, V.D., and Surgeon-Captain E. Ryan. Both classes were so well attended on the first night that the brigade-surgeon announced that no more men would be taken in either class after Monday, Oct. 10th. The officers' class recently held at the headquarters of the 1st Middlesex Rifle Volunteers has also been well attended and nearly 300 officers have now passed through the school.

THE LATE SPANISH-AMERICAN WAR.

The *Saturday Review* of Oct. 1st contains the first of what promises to prove an interesting series of articles on the above war by "an eye-witness." It is certainly lamentable to read of the state of things which apparently prevailed among the American troops. The writer says that the saddest instance of American official blundering was connected with the Army Medical Department, with which he proposes to deal in his article next week—the current number of the *Saturday Review*.

DEATHS IN THE SERVICES.

Brigade-Surgeon James Edward Tierney Aitchison, M.D. Edin., C.I.E., F.R.S., LL.D., Bengal Army (retired), on Sept. 30th, at his residence at Kew, in his fifty-fourth year. He entered the Bengal Medical Service in 1858 and served in the Afghan war of 1878.

It is announced that the tenure of appointment of the Directors-General of the Army Medical Department and the Army Veterinary Department shall in future be for five years unless the term is specially extended by the Secretary of State for War for a further period not exceeding two years.

In consequence of two officers of the Militia Medical Staff Corps having been seconded for service in the Niger Protectorate under the Foreign Office there are now vacancies for commissions.

Lieutenant-Colonel A. Kirwan, retired pay, R.A.M.C., has been appointed to the medical charge of the Leicestershire Regimental District.

"Audi alteram partem."

"THE PRACTICAL APPLICATION OF BACTERIOLOGY TO COMMERCE."

To the Editors of THE LANCET.

SIRS,—May I be allowed to add a footnote to the leading articles which appeared in THE LANCET of Oct. 1st? I have read with especial interest your remarks upon the practical application of bacteriology to commerce, as I have had occasion to follow the developments which have taken place in this branch of bacteriological investigation during the past few years. You have rightly emphasised the benefits which the labours of Pasteur have conferred on the industries of his country. This side of Pasteur's work has received too little attention in England though it has had more far-reaching effects than even his investigations upon disease. The impulse derived from the researches of Pasteur in this field has made itself but little felt amongst us if we take the achievements of foreign laboratories as a standard. I need only refer to Hansen's investigations which led to the introduction of pure yeast cultures and reduced brewing to an accurate scientific operation. The work also which is being carried on in Denmark and America upon dairy bacteriology is gradually placing the methods employed in the dairy on an accurate basis. In Germany the possible utilisation of bacteria in agriculture is receiving the closest attention, as well as the study of the living agents which play an active part in various fermentations—e.g., tanning, wine preparation, tobacco manufacture, &c. In this field of work we lag behind the continent and America. The methods practised on Lord Vernon's estate furnish an example of what must be done if our dairy produce is to be brought to the level of that of Denmark.

The laboratory of M. Duclaux at the Pasteur Institute, along with the instruction of M. Fernbach, is worthily upholding the Pasteur tradition and is yearly training a body of men to approach their work in a scientific spirit. M. Calmette at the Pasteur Institute of Lille, which I have visited, is carrying on the same work and is cordially supported by the municipality and the manufacturers of the district. M. Calmette's investigations upon snake venom are widely known, but fewer know of his investigations upon alcoholic fermentation, which promise to reduce distillation to a scientific method.

It may be of interest in this connexion to announce an important departure at the British Institute of Preventive Medicine. A large laboratory has been assigned to instruction and investigation in zymotechnical questions. In this laboratory it is hoped that the agriculturist, brewer, and chemist may find the instruction individually required for successfully employing the living agents of fermentation. Investigations will also be undertaken under competent direction, and it is hoped that when the department is fully organised many will be willing to avail themselves of its facilities and that it will become a centre of useful work on the lines you have indicated. The article upon a Central Bacteriological Laboratory for London has also a special interest for the British Institute of Preventive Medicine. This institute was amongst the first to undertake the examination of material on behalf of medical men and sanitary authorities and the requests for its aid have come from all parts of the United Kingdom. The institute is likewise doing similar work for important London districts—e.g., Marylebone, St. Pancras, Islington, Fulham, &c.—as well as conducting the systematic examination of water-supplies for a number of public bodies. The work is being done economically and with satisfaction to the various authorities concerned. The plea for a central laboratory for such investigations must appeal strongly to the community. At the same time, as you suggest, the need could be adequately and more economically met by utilising existing institutions. This institute was established by private enterprise to provide a national centre for bacteriological investigation and in its new home at Chelsea possesses a bacteriological department, a zymotechnical laboratory, research rooms, and a laboratory which it is desired to make a centre for investigations bearing on the public health. The question is a natural one: Why multiply new institutions if the work it is desired to do can be satisfactorily and economically carried out by those already in existence? The fees received would help to support a staff of men devoting their whole time to investigation and would be the means of increasing the output of valuable research work. I trust, having regard to the importance of the matters in question, you will allow me to take the opportunity of stating my views and of saying how heartily I endorse the suggestions you have made for the direction of this new movement. I am, Sirs, yours faithfully,

ALLAN MACFADYEN,
Director, British Institute of Preventive Medicine.
Grosvenor-road, London, S.W., Oct. 3rd, 1898.

"VITALITY."

To the Editors of THE LANCET.

SIRS,—In his letter published in THE LANCET of Sept. 10th Dr. Lionel Beale does not meet the objections I have advanced against his views on vitality. I ask, whence comes the augmentation in the sum of vitality possessed by an organism as it develops from a one-celled to a myriad-celled being, unless it be from the food and oxygen conveyed to it from without? For vitality, as Dr. Lionel Beale employs the term, is, I take it, a species of force, and force cannot be created out of nothing. Seeing, moreover, that force cannot be annihilated, what becomes of the vitality of an organism after death unless it be transmitted into some chemical, physical, or kindred force? But Dr. Beale would deny the possibility of such transmutation since he denies any correlation between vitality and the forces belonging to matter.

I contended that Dr. Lionel Beale is illogical in assuming that bioplasm is structureless, but my reason for this is not the one given by him. I say that in our journey into the world of the infinitesimal we, with our very limited means of investigation, come sooner or later to a point at which we cease to detect structure, but that this is a purely arbitrary point, that it merely marks the limit of our perceptions and *bears no relation whatever to any grand fact of nature.* Does Dr. Beale suggest that the nucleus of the ovum and spermatozoon that are destined to develop into a Newton or a Shakespeare cannot possess an elaborate structure simply because they appear so small to us? If he does I must repeat my assertion that his position is wholly illogical. The nucleus of the genital cell is no nearer the limit of smallness than it is to the limit of greatness, for we may go on dividing or doubling it *ad infinitum* without reaching the confines of the one or the other. We must not be hampered in our biological speculations by false conceptions of space. Bearing these considerations in mind Dr. Lionel Beale must of necessity admit that his bioplasm *may* be structural, and if he admits this he will more readily allow the possibility of "vitality being a peculiar play of forces belonging to the inorganic world," and depending upon the nature and arrangement of the atoms of bioplasm (= structure) and other purely physical conditions.

Dr. Lionel Beale asks what, on the assumption that "vitality is a peculiar play of forces belonging to the inanimate world," governs and controls these forces in living matter. I would reply that the behaviour of living matter depends upon the material conditions as represented by the living matter and its environment, just as the behaviour of a planetary system depends upon material conditions—upon the size and relative position of the worlds, &c., constituting it (= structure) and upon its relations to other systems (= environment). To call in a power, a governing, controlling, in short, an intelligent agency, which is quite distinct from the forces of the inanimate world, is but to deepen the mystery of life. Dr. Beale, instead of seeking to explain the behaviour of living matter by reference to known laws, postulates a power which is as great a mystery as the thing he seeks to explain by it.

I ought here to say that I used the term "spiritualist" not in the vulgar but in the modern psychological sense, as distinguished, namely, from "materialist." The former assumes that mind can act upon matter and the latter that matter can produce mind; and I compared Dr. Beale to the spiritualist in that he assumes that vitality is a controlling agency existing apart from matter, but yet capable of guiding its operations so that it shall *live.* By thus assuming that the immaterial can act on the material Dr. Beale takes up

a position which many great thinkers have regarded as untenable. I am, Sirs, yours faithfully,

Wimpole-street, W., Sept. 26th, 1898. HARRY CAMPBELL.

CONSCIENTIOUS OBJECTION AT KEIGHLEY.

To the Editors of THE LANCET.

SIRS,—We have this week the first example of the wholesale working of the new Vaccination Act in an anti-vaccinationist community. Keighley has for more than twenty-five years been one of the strongholds of anti-vaccination. On Tuesday, Oct. 4th, 660 parents and guardians succeeded in gaining exemption for about 1670 children. At a similar court to be held on Oct. 18th no doubt a large number of additional exemptions will be granted. As the population of Keighley is about 35,000 it will be seen how large a proportion of the population has already exercised its right (granted by the wisdom of Parliament) to allow children to become potential dangers to public health.

Conscientious objectors forsooth! How were the proceedings carried out? The parents were brought into court in batches of from 10 to 20 at a time and asked whether they had conscientious objections. Some replied verbally, and in many cases a nod of the head was deemed sufficient proof of their deep-rooted convictions. A fee of 2*s.* was exacted in each case. With such rapidity were the proceedings carried out that in two courts the whole of the 1670 children were exempted in two hours and a half! A pure farce from beginning to end. It savours more of a Gilbert and Sullivan comic opera than the administration of laws of the realm. All these people and their children have now received the sanction of the Government to be a medium for the maintenance and diffusion of small-pox, whereas before the passing of the present Act they were tolerated by a negligent and apathetic board of guardians. One wonders how long the comedy will go on before it becomes a tragedy and wakens up the Government to a due sense of its responsibility. Should there be a serious outbreak of small-pox among these "conscientious objectors" the promoters and supporters of the exemption clause among the Government must consider that the responsibility lies at their door. If vaccination is of any use let it be absolutely compulsory, with imprisonment as punishment for non-compliance; if, on the other hand, it is useless, let it be voluntary.

I am, Sirs, yours faithfully,

Oct. 6th, 1898. CLEMENT ROGERSON, M.D. Lond.

"HOSPITAL REFORM ASSOCIATION."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 10th Mr. T. Garrett Horder, the hon. secretary of the Hospital Reform Association, solicits the opinion of your readers as to "whether it would be desirable and useful to hold a congress in London some time during the ensuing year to discuss the subject." I, for one, answer decidedly, Yes, and it is sincerely to be hoped that both the medical profession and the subscribers who should be so deeply interested in this important question will combine in making the meeting a success. I have been moving in this matter for the last few years and I feel convinced that we cannot too often draw the attention of the public to the increasing evil of hospital abuse.

I am, Sirs, your obedient servant,

Hove, Oct. 3rd, 1898. FRANCIS J. A. WARING.

RESONANT SPLEENS.

To the Editors of THE LANCET.

SIRS,—In his interesting case reported in THE LANCET of Oct. 1st, p. 866, Dr. J. Michell Clarke remarks that a "small area of tympanites beyond the stomach to the left over the tenth and the eleventh ribs was difficult to account for." The situation described and that depicted in Fig. 2 corresponds so exactly with the normal splenic surface area that in the absence of a reference to the presence of any splenic dulness the view might perhaps be entertained that the tympanitic note was due to the spleen. This suggestion is made on the strength of a series of observations in which the dulness of the spleen was converted into a boxy tympanitic resonance. The resonance referred to by Dr. Michell Clarke may have been brought about in an entirely different way; but the case reads as though it might illustrate a peculiarity which it may be sometimes useful to bear in mind at the bedside and to which reference has been made in a note on the Diagnostic Uses of Percussion of the Vertebral Spines,[1] and in a Lecture to Advanced Students on Pleximetry and on Pleximetric Bones and Viscera,[2] where the "boxy spleen" is further discussed.

I am, Sirs, yours faithfully,

Curzon-street, Mayfair, Oct. 3rd, 1898. WILLIAM EWART.

SPHINCTER STRETCHING IN CONSTIPATION.

To the Editors of THE LANCET.

SIRS,—The subjects of fissure *in ano* have usually suffered from prolonged constipation. This would seem to be permanently relieved by dilatation of the sphincter and that to an extent which is incompatible with the supposition that hygienic and drug treatment have been the only agents in causing success. The consideration of this fact has led me to employ sphincter stretching in several cases of intractable constipation in children with, so far, good results. I would suggest that there are two factors making for this result: (1) the destruction of what was mechanically a relative stricture; and (2) the presence of a nervous connexion between the anal orifice and the large bowel analogous to the so-called polarity of the uterus. I have been unable to give this method a trial in adults and should be glad to learn the experience of others in the matter.

I am, Sirs, yours faithfully,

SIDNEY VINES,
Assistant Resident Medical Officer, St. Mary's Children's Hospital, Plaistow, E.

Plaistow, E., Oct. 2nd, 1898.

SANITARY INSTITUTE CONGRESS.

To the Editors of THE LANCET.

SIRS,—The newspaper reports of the Congress at Birmingham are in error in attributing to me a motion regarding sanitary administration in Ireland. The motion was made by Mr. J. H. Fergusson, Killygordon, Donegal. Your insertion of this correction will oblige.

I am, Sirs, yours faithfully,

Glasgow, Oct. 3rd, 1898. JOHN C. MCVAIL.

THE LIMITS OF PROFESSIONAL SECRECY.

To the Editors of THE LANCET.

SIRS,—Some months ago I was called upon as a Poor-law medical officer to attend an unmarried woman suffering from septic metritis. I found the uterus to contain a decomposed fœtus. She absolutely refused to communicate her condition to anyone except a woman (a relation) in attendance. Her state was too serious to admit of delay and I could not refuse to attend her without divulging her condition to the board. I therefore procured the help of two colleagues, curetted the uterus, and returned the case as "septic metritis." In consequence of neighbourly gossip the guardians have now applied to me for information as to whether the late illness was produced by her own misconduct. I refuse all information as a violation of professional secrecy. Can you advise me if any conditions of relationship or employment warrant a medical attendant giving such information to any third person and if any statutory or common law protection against action is afforded to a Poor-law medical officer in such a case? Could I have acted otherwise in dealing with the matter? I am, Sirs, yours faithfully,

Oct. 2nd, 1898. "JOHN DOE."

*** We consider that "John Doe" was quite right in not divulging the cause of the metritis. He is not a censor of morals as well as a Poor-law medical officer. If he makes the return asked for we doubt if he would be protected by "privilege." Probably a defence in a civil action of giving information "without malice" would be successful, but we

[1] THE LANCET, July 2nd, 1898, p. 23.
[2] Clinical Journal, July 13th, 1898.

Digitized by Google

advise him not to run the risk. If he is pressed for further information he should refer the matter to the Local Government Board and await events.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Progress of the Plague Epidemic.—Statistics of Inoculation.

THE heavy rainfall of the past week in Bombay city, amounting to over 20 in., has been accompanied by a slight decrease in the total mortality. The official returns, however, show 175 deaths from plague against 168 last week, and as the total mortality is above the average by considerably more than this number of plague deaths there is strong reason to suppose that many cases are recorded as due to other diseases. This especially applies to the Mohammedans, whose record of plague deaths is obviously incorrect. Registration is admittedly very faulty and the total number of weekly deaths is the only thing which can be relied on. It is unfortunately too plain that plague is again developing, although the successive increases each week have not been large.

In the Madras Presidency a few cases keep cropping up, but it has not yet been officially declared in the city. The excessively high rate of mortality is, however, very suggestive. Some disturbances have occurred at Bangalore, panic with regard to plague measures having seized the people, and troops have had to be called out.

In the Bombay Presidency 3637 cases and 2749 deaths were recorded against plague during the past week. The total mortality from plague since the commencement of the epidemic in September, 1896, is 105,512.

With regard to inoculation remarkable success is reported from Hubli. It is stated that no less than 32,000 people have gone through the process and that during the existing outbreak in that city only 69 of these have been attacked, while among the 8500 uninoculated there have been 417 attacks. If these figures be reliable they speak for themselves. In the district around, however, there has been a large number of deaths—the Dharwar district, in which Hubli is situated, being credited with 1047 cases and 892 deaths. To show how differently inoculation has been received at different places there remains only to compare Calcutta and Bombay, each with about 750,000 inhabitants and with about 2000 and 20,000 persons inoculated respectively, against Hubli, with a population of about 40,000 and no less than 32,000 inoculations. In Bombay there have been 27,305 deaths from plague and in Calcutta about 200. Amongst the inoculated in Bombay there were :—

Sept. 16th

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Birmingham Medical School.

THE present session was opened on the 3rd inst. at Mason University College, the inaugural address being delivered by Professor Michael Foster of Cambridge.[1] The dean of the medical faculty, Dr. Windle, presided and a large attendance included the Lord Mayor of Birmingham (Mr. C. Beale), several members of the council, a number of the professors, and others interested in the cause of medical progress. The address dealt with the rise of universities and guilds, their development, aims, and functions. A sketch was given of the proposed university for Birmingham, in which it was insisted that it should not be an educational institution directed by the principle of payment by results; nor should it be a system of classes "which proposes at the least expenditure of time, money, and, it may be added, of brains to drive a head through the same narrow gateway of this or that formal examination." The encouragement of learning and research was indicated as the object to be kept in view—the spirit of inquiry, the guiding spirit. Some valuable hints and counsel as to the future were given and attentively listened to. The address was marked by a thoughtful accuracy of expression and intimate experience of the subject, the outcome of the wise and deliberate reflection of a master mind. We hope to see it in a permanent form, so that we may be enabled to dwell upon the eloquent truths it proclaimed. The prizes of the clinical board will be distributed by Sir William Mac Cormac on the 6th inst. at the General Hospital. The same evening Sir William Mac Cormac is to be entertained at dinner by the members of the Midland Medical Society, who celebrate their jubilee on this occasion. They look forward to the honour of having the learned President of the Royal College of Surgeons of England as their guest. The inaugural address of the same society will be given by Mr. Treves on the 20th inst.

Oct. 4th.

[1] See page 915 of this issue.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Insanitary Board Schools.

DR. WOODCOCK, who is a member of the Manchester School Board, did good service at the meeting of the board held on Sept. 20th by calling attention to serious sanitary deficiencies in several of their schools. The playground into which 198 boys are turned out for air and exercise at one school contains 180 square yards. At the same school 212 girls have to find space for fresh air and active games in 147 square yards. A sub-committee has recommended the increase of these "playgrounds" to 264½ and 239½ square yards respectively and it can be imagined how the children will revel in the sense of boundless space when these additions are made. In one class-room, 15 ft. 9 in. by 11 ft. 9 in., affording proper accommodation for 18 children, there were present when Dr. Woodcock visited it 50 children and their teacher, and in the boys' department he found 27 boys and their teacher in a room with proper accommodation for 18. At another school, in which the only ventilation is by open windows, the odours from a deposit of manure are wafted in from the confined space at the back of the buildings and this manure is stirred up for removal, it is said, three times a week. At St. Michael's Board School in Hulme, "the cellar communicating with the offices was occupied by 57 boys and 2 teachers. There were 5 gas-lights burning." The boys had to wear their caps as a protection against the draught from the open windows, through which the filth from the street "was freely blown." In an adjacent room he "found 30 boys and their teachers in a 'poisonous den'—a dark room below the level of the street, 16 ft. by 11 ft., and only 8 ft. high. There is not an inch of playground to this school." This state of things, of which examples could easily be multiplied, has not been suspected by the ratepayers of Manchester, and now that it has been at last revealed by a medical member of the board no doubt some energy will be displayed in removing evidences of—to say the least—gross disregard for the bodies, whatever may be the case as to the minds, of the poor children under the fostering care of the School Board. One of the older members of the board said, truly enough, that "the statement of Dr. Woodcock constituted a terrible indictment." Some people complain of lavish and unnecessary expenditure on the part of the School Board, but clearly there has been none too much done for the health of the children. More attention should be given to securing space and light, even if it should entail less expenditure on the costly decorative features so attractive to public-spirited members of "boards." It may be well, perhaps, if some candid friend will look to the sanitary conditions of the voluntary schools.

Typhoid Fever at Leigh.

A serious outbreak of typhoid fever has taken place at Leigh, near Manchester. Up to a few days ago 28 cases had been reported and several deaths had occurred. The Leigh District Council Health Committee are urging the Leigh Joint Hospital to complete their typhoid ward as quickly as possible. There is also a "rivers pollution" question in that neighbourhood, and the Hindley District Council have received 28 days' notice to stop the discharge of untreated sewage into the West Leigh brook under threat of legal proceedings. Whether this is connected with the outbreak does not appear, but striving for purity of streams is always good and increasingly important.

Poisoning from Bad Food.

Deaths from "bad food" have been unusually frequent during the hot period through which we have just passed. The city coroner held an inquiry on Sept. 22nd as to the death of a young fellow, aged eighteen years, who ate some pork for supper on the Monday and died on the Tuesday evening from gastro-enteritis. He was seized during the night with vomiting, diarrhœa, and cramp, and in the opinion of Dr. E. S. Reynolds, who made a post-mortem examination, "the pork said to have been eaten ..... on Monday evening might have set up the disease." The evidence of the person who is said to have sold the pork throws a little sidelight on food customs in the "slummy" parts of the city. The meat was bought on the Friday evening and kept on a stove in the back kitchen till Monday morning, when it was cooked. She "gave 2*s.* 3*d.* a dozen for it, which was a very good price." 2½*d.* a pound may have been a very good price for that special piece of pork, but most of us would look with suspicion on meat offered at such a "sacrifice."

"Carbolic Poisoning."

"Carbolic poisoning" is such a common newspaper heading that it is apt to pass unnoticed. The city coroner made some remarks on it, as he has frequent opportunities of doing, at an inquest on Sept. 23rd. The deceased and his wife for some time past had lived a miserable life and had drunk heavily; the latter came drunk to the court to give evidence which, however, was not taken. The man, forty-three years of age, goaded by drink and misery, bought sixpennyworth of carbolic acid, drank it, and threw away the bottle. He was taken to the infirmary, where he died. The coroner spoke of the frequency of this mode of suicide, which he could scarcely understand, seeing that it was like swallowing red-hot coals. The jury suggested that some restriction should be placed on the sale of carbolic acid, and he said "the legislature had no more contemplated that people would poison themselves in this way than that they would swallow live coals," but these cases were becoming so common that he thought its indiscriminate sale should be prevented. A cynic might perhaps say that the lives lost through carbolic acid are scarcely worth preserving, but that ought not to be the attitude of a "parental Government."

Vaccination: a Ray of Light.

At the meeting of the Salford Board of Guardians on Sept. 23rd permission was given to terminate the tenancy of certain vaccination stations on the introduction of home visits by the vaccination officers. One of the guardians distinguished himself by a prose pæan on the discomfiture of the vaccinationists. He congratulated the board that in the future they need not imprison people for not vaccinating their children. They never had done so and now there would be really no necessity for it—i.e., they never had done what there was a necessity for their doing. "The new law respected every man's conscience" (perhaps he should have said every man's ignorance and prejudice, as conscience has so very little to do with it) "as it ought to do, and he was glad they had got this ray of light in the nineteenth century." We cannot congratulate Salford on the possession of a guardian whose ray of light seems to be darkness.

Sept. 30th.

DEVONPORT WORKHOUSE.—On Sept. 30th the Devonport Board of Guardians discussed the alleged dark and insanitary condition of the punishment cells at the workhouse, and eventually it was decided to ask the Works Committee to effect certain improvements in them.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Vacant Professorship of Midwifery and Gynæcology in University College, Liverpool.

THE appointment by the Council of the Senatus Academicus to the professorship of midwifery and gynæcology in University College which became vacant by the demise of Dr. John Wallace on Sept. 1st is looked forward to with some interest. The candidates for the post are Dr. Henry Briggs, Dr. T. B. Grimsdale, Dr. Arthur Wallace (son of the late professor), and Dr. John E. Gemmell. All the four applicants are fully qualified for the office, but it is anticipated that the contest will lie between the first two candidates. As the winter session has already commenced the election will take place at an early date.

The West Derby Board of Guardians and the Treatment of Tuberculosis.

The West Derby Board of Guardians are taking an active interest in the question of the "open-air" treatment of tuberculosis. On the initiative of Mr. J. C. Bradshaw, the chairman of the Mill Road Infirmary, the board have addressed a communication to the medical officer of health of Liverpool, enclosing a copy of a report from Dr. Raw, the medical superintendent of the Mill Road Infirmary, on the open-air treatment of tuberculosis. The guardians, however, are not satisfied that the number of cases under treatment in their infirmary is sufficient to justify them in establishing a separate institution on the lines laid down by Dr. Raw, but they would be glad if Dr. Hope would lay the report before the health committee in the hope that the committee may consider the advisability of establishing a municipal institution for the out-door treatment of tuberculosis on similar lines.

The late Right Hon. Sir Arthur B. Forwood, Bart., M.P.

The late Sir A. B. Forwood, who was an alderman of the city council, took an active interest in local sanitary affairs and during his chairmanship of the health committee, a post filled by him for many years, he brought about many important improvements contributing to the health of the city in general. He was largely instrumental in retaining the Ladies' Charity and Lying-in Hospital for maternity cases, although an active party moved to change its constitution with the purpose of converting it into a hospital for gynæcological patients only, assigning as a reason for the proposed conversion the excessive rate of mortality among the lying-in patients (which was afterwards discovered to be due to defective drainage). As a result of the contest between the opposing parties among the subscribers to the charity it was decided to separate the departments of midwifery and gynæcology and to locate their respective patients in different buildings. This led to the foundation of the hospital for women in Shaw-street in 1880, which was placed under separate management and is devoted exclusively to gynæcological cases. The lying-in patients were soon afterwards transferred to a new building in Brownlow-hill, adjoining University College. The old building in Myrtle-street was purchased by the committee of the Cancer and Skin Hospital, and when making necessary alterations in the basement it was discovered that the drainage was in a most insanitary condition, fully accounting for the excessive mortality among the lying-in patients in past years. The lying-in hospital has done much good work and since its removal to its present habitation the health of the patients has been excellent.

The Conscientious Objector "at bay."

The "conscientious objector" received his first check in Liverpool last week at the hands of two county justices who failed to be convinced that "disbelief in the efficacy of vaccination" by an applicant for exemption was a sufficient plea to put forward to enable them to issue their certificate. On a subsequent day the same individual renewed his application through counsel but the magistrates could not be persuaded to reopen the case. The presiding magistrate, in giving the decision of the bench on the application, said that contempt for vaccination was not in the opinion of the justices a matter of conscience but one of opinion, a plea which was not provided for in the Act of Parliament. A similar case came before the Lancaster magistrates during the week with a similar result.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

New Hospitals in Aberdeenshire.

THE Aberdeen District Committee of the County Council has been authorised to acquire a site (five acres) at Summerfield, near Old Skene Road, on which to erect a new hospital. Tenders have also been accepted for building additions at Gordon Hospital, Ellon.

Aberdeen Water-supply.

The corporation's water committee, having considered the bacteriological and analytical reports on this subject—recently noticed in THE LANCET—resolved that before deciding upon any works for the improvement of the present supply inquiry should be made as to the practicability and cost of obtaining a sufficient supply of pure water from a source other than the River Dee. In this connexion the committee's attention has been called to the question of obtaining a supply from the River Avon, near Inchrory (about 60 miles from the city), and the committee accordingly resolved to recommend that the town council should remit to them to report upon the subject of the supply from that source, it being understood that they are to be entitled to obtain such professional assistance in connexion with the matter as the committee may deem necessary. The town council on Monday last adopted the report.

Proposed Public Slaughter-house at Aberdeen.

The corporation's slaughter-house committee have recommended that a private Bill be introduced in the next Parliamentary session authorising the municipality to erect at Central Park, Kittybrewster, on ground already belonging to the town council, a public slaughter-house to supersede all the existing private slaughter-houses, the borrowing power to be sought by the Bill to be £50,000. On Oct. 3rd the town council deferred the settlement of the matter owing to pressure of other business.

Aberdeen Corporation Lodging-house.

As this extensive building is almost finished, the rates per cubicle per night have been fixed, the charges varying from 6*d.* to 4*d.* A superintendent, assistant superintendent, and other servants are to be appointed at an early date.

Oct. 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal University of Ireland.

THE medical examinations of the Royal University are now in progress, the lists of candidates who have passed the second examination in medicine having just appeared.

St. Vincent's Hospital, Stephens-green, Dublin.

The address inaugurating the medical session at this hospital was delivered by Mr. J. S. McArdle on the 4th inst.

Mater Misericordiæ Hospital, Dublin.

The clinical lectures of the session commenced at this hospital on Oct. 3rd. The new prospectus includes arrangements by which the two operation theatres will for the future be used simultaneously. The greatly increased number of patients who now seek admission to the hospital for operation has rendered the addition of a second operation theatre necessary. On Oct. 3rd a lithotomy, by which no less than 117 separate and distinct uric acid calculi varying in size from that of a filbert to that of a pea were removed, was performed by Dr. Coppinger, one of the surgeons to the hospital. The patient, a man aged sixty-four years, is progressing well.

The Irish Workhouse Association.

A meeting of the executive committee of this association was held on Sept. 29th, the president, Lord Monteagle, being in the chair.

Mr. T. W. Russell, M.P., on Citizenship.

At a conference in Belfast on Sept. 28th Mr. T. W. Russell, M.P., Parliamentary Secretary to the Local Government Board, in an address on the Duties of Citizenship, spoke of the question of the Poor-law system and in doing so praised very highly the way in which in England this cast-iron system is being transformed. He said that in everything human the Irish workhouse is as inferior to the companion institution in England as it is possible for an institution to be. He also spoke of the question of sanitation and, engaged in, as he was, and having some responsibility for, the Public Health Department of the sister country, he could affirm that the science of sanitation was in its infancy in Ireland. He said in such questions as water-supply, housing of the very poor, and sewage Ireland compared very unfavourably with England. The reform of all these questions formed part of the duties of good citizens.

Londonderry Dispensary.

At a meeting of the Londonderry Dispensary Committee held on Sept. 30th Dr. Cunningham was elected medical officer of No. 1 district, in succession to Sir Acheson MacCullagh, M.D., who has been appointed an Inspector under the Local Government Board.

Effect of the Local Government Act on the Administration of the Cork General Hospitals.

At a meeting of the trustees of the Cork South Infirmary held last Friday, Mr. Maurice Healy, M.P., occupied the chair, and after the special business of the meeting had been disposed of the treasurer requested the chairman to inform them as to the alterations in the government of the hospital to result from the passing of the Local Government Bill. Mr. Healy then explained that the present board of trustees, consisting of ex-officio and elected trustees, would continue to exist, with the exception that the church dignitaries and rectors who are now trustees in virtue of their ecclesiastical offices will cease to be ex-officio trustees. The other ex-officio members will continue to be trustees and the elected members will as heretofore be eligible for re-election by the subscribers annually. But the functions of the board of trustees so constituted will be entirely different from those of the board of trustees which now administers the affairs of the hospital. After the Local Government Act comes into operation a new board of governors will be appointed, and practically the only function the board of trustees, as distinct from the board of governors, will have to perform will be to elect a certain number of governors to represent the ordinary subscribers to the hospital. The new board of governors will comprise three sections, one consisting of the members elected by the board of trustees, another consisting of those nominated by the County Council of the County of Cork, and a third consisting of those nominated by the County Council of the Borough of Cork. The number of governors to be elected by each section will be decided by the Irish Local Government Board, and the latter Board will doubtless be mainly influenced by the amount of the contribution from each body represented to the funds of the hospital. For years past the county Grand Jury and the Cork Corporation have each contributed £700 a year voluntarily towards the maintenance of the Cork South Infirmary, and under the Local Government Act the county councils will be compulsorily obliged to contribute a similar amount unless the Local Government Board decides otherwise. Furthermore, the County Council for the County of Cork will have power to contribute another £700 a year towards the maintenance of the South Infirmary or any other hospital which in their judgment is deserving of support. A vote of thanks to Mr. Healy for his lucid explanation was unanimously passed.

Erratum.—In the last letter, under the heading "The Health of Belfast," in the fourth line "341" should have been *34*.

Oct. 3rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Agglutination of Koch's Bacillus by Human Serum.

AT the meeting of the Academy of Sciences held on Sept. 19th MM. S. Arloing and P. Courmont communicated a paper dealing with the final stages of their researches upon the agglutinative action of human serum upon the bacillus of Koch. To obtain this reaction by means of the blood of a tuberculous subject certain precautions have to be observed which can be neglected when dealing with other diseases, such as typhoid fever for instance. The serum must be used with fully developed cultures, of which only the upper layers are taken, for the lower layers almost always contain extraneous growths. To get a marked reaction

Digitized by Google

perfectly fresh and colourless serum must be employed. The blood collected with aseptic precautions is first centrifugalised so as to separate the clot. The reaction is made to take place in sterilised tubes of very small diameter, which are laid on their sides in a sloping position so that the clusters may fall more rapidly and at the same time cover a larger area of the tube. With every serum three mixtures of different strengths are made—i.e., 1 drop of serum to 5 drops of culture, 1 to 10 and 1 to 20. The agglutinative action produced in mixtures more concentrated than 1 to 5 or less than 1 to 20 has no diagnostic significance. The interval before reaction takes place is variable, but as a rule it takes longer than in typhoid fever. The tubes are examined two hours, ten hours, and twenty-four hours after the mixture has been made. Any changes observed at a longer interval than twenty-four hours may be neglected. The tubes are examined both with the naked eye and under the microscope. A control tube of culture without any admixture of serum should always be used, which ought never to show any precipitate. At the end of twenty-four hours reaction is considered as certain if the tube contains well-marked clumps and the liquid is quite clear or presents only a trace of cloudiness. Even with all these precautions the reaction is by no means easy to get and it is always as well to compare results with the agglutination obtained with the serum of a patient undoubtedly tuberculous. The results obtained by Arloing and Courmont are remarkably interesting but are not yet sufficiently definite to draw absolute conclusions from. They examined 26 patients suffering from advanced tuberculosis, with high temperature and other infective signs. Of these 92 per cent. gave the reaction, 69 per cent. with a mixture of 1 in 10 or 1 in 20 and 23 per cent. with a mixture of 1 in 5. In 2 cases out of the 26 where no reaction was obtained the patients were in a condition of very advanced tuberculosis, a phenomenon of which the cause is at present to seek. Out of 22 patients suffering from slight pulmonary or pleural diseases 95·5 per cent. gave the reaction, 82 per cent. with mixtures of 1 in 10 or 1 in 20 and 13·5 per cent. with mixtures of 1 in 5. The only person who did not react was one with a pleuritic effusion and marked pleural thickening in whom tubercle was very doubtful, inoculation of the pleuritic fluid into a guinea-pig having produced no effect. Of 12 patients suffering from surgical tuberculous affections 50 per cent. reacted very strongly and 50 per cent. feebly; of 21 patients suffering from various disorders 14 gave no reaction and 7 a very feeble one; of 13 typhoid fever patients 6 gave a negative result; of those which did react 2 at least were suspected of being tuberculous; of 16 patients aged from eighteen to thirty years, and all apparently healthy, a reaction was given in 5 instances.

Hospital Abuse in Paris.

For a long time past the medical men of Paris have protested against the system whereby the gratuitous advice to be obtained at hospitals is abused. A system only intended for the poor and needy is exploited by persons in easy circumstances, thus depriving the medical practitioners of their lawful gains. The syndicate of medical practitioners in the Department of the Seine has sent in many unavailing protests to the Director of the Assistance Publique asking that either he should prevent any patient who did not bring incontestable proof of poverty from attending the hospital or that he at least should put up a notice that persons in easy circumstances who attended in this way and robbed both the poor and the medical men should be prosecuted and fined. In the poorer quarters of Paris many a medical man is willing to see working-class patients for a fee far less than the amount which the average working man spends daily in drink; nevertheless, it is considered quite right for all such workmen to attend the hospitals for nothing. Not only, however, do workmen attend but also tradesmen in easy circumstances and far richer people, especially when the medical man for the day happens to be a well-known practitioner. In view of the fact that all these protests have been in vain Dr. Variot, the head physician to the Hospital Trousseau for Sick Children, has decided to charge every person who is well off and comes to the hospital for gratuitous advice the sum of 20 fr. The fees thus collected will be expended in buying toys and delicacies for the poor children in his wards. Not long ago two ladies richly dressed applied at his clinic, bringing with them a child whose frock was trimmed with lace. On being asked whether they were poor they replied in the negative and Dr. Variot thereupon demanded 20 fr., being his usual fee for a consultation at his own house. They angrily refused and went away uttering threats. Some days afterwards they sent in a complaint to the Director of the Assistance Publique as to the behaviour of the medical man who had refused to give them gratuitous advice. The director promptly demanded an explanation from Dr. Variot, who replied that he did not in the least regret what he had done and that he should act in a like manner in every similar case until the director took steps to see that the interests of the poor and also of medical men were safeguarded.

Medical Aid in Theatres.

The prefect of police has just issued an edict with regard to the medical organisation for the theatres. Up to the present time the choice of medical men bound to be present in turn at theatrical representations so as to be able to give aid in case of any accident occurring among the audience or staff of the house has been left to the manager save in the case of the four national theatres—i.e., those subsidised by the Government. It has happened that on several occasions when an accident did take place that there was either no one in attendance at all or else that the proper medical man had supplied his place by some non-medical friend who was absolutely useless. The prefect has therefore given orders that in future all nominations to these posts must be submitted for his approval—a regulation which has been the cause of a great outcry among medical men. Most likely, however, the prefect only wishes to have the opportunity of being able to revoke the appointments of such medical men as shirk their duties, for hitherto the managers have appointed their own friends and have not been able to exercise any serious control over them.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Antitoxin Monopoly.

PROFESSOR BEHRING'S application for a patent for his antitoxin, which was so severely criticised in a leading article in THE LANCET of August 27th, has been much discussed in the German newspapers, both lay and medical. The charges made by the American papers induced Professor Behring to declare in a periodical published in Marburg, his place of residence, that he did not concern himself about what the American chemists had said against him because they had spoken *pro domo*. His claim for a patent was legal and he could not understand that to make profit out of an invention in a legal way might be an immoral action. The American public would not suffer in consequence of his patent, as the serum would now be obtainable of better quality and at lower prices than before. These views of Professor Behring are strongly disapproved of by the *Münchener Medicinische Wochenschrift*, the leading medical paper of South Germany, which maintains that some methods of making money, though legal enough in themselves, are nevertheless impossible for a medical man who desires to conform to the laws of medical ethics. The criticisms of the American and English press were to be regretted, but were not unfounded. Among the leading non-medical papers, the *Berliner Tageblatt* has severely blamed Professor Behring. In an article entitled "Science and Business" a medical contributor to this periodical asked: "What would have become of the ophthalmoscope if Helmholtz had made a claim to patent his invention? What would have become of the methods of immunisation devised by Pasteur, or of the antiseptic dressing introduced by Lord Lister, if these gentlemen had acted like Professor Behring? Medical men ought not to be dealers in medical commodities." To these charges Professor Behring has replied, writing in the *Deutsche Medicinische Wochenschrift*. In his usual plain language he said that Helmholtz of course could not have attempted to patent the ophthalmoscope as there were no patent laws at that time; what Pasteur and Lord Lister would have done, supposing that it had been possible for them to obtain a patent for their discoveries, he really did not know, and he wished to ask if the medical correspondent of the *Berliner Tageblatt* knew.

Digitized by Google

From his personal acquaintance with those two gentlemen he thought himself entitled to suppose that they would have declined to defend the interests of foreign traders. He went on to mention that he did not belong to the medical profession in the strict sense of the term, as he was not engaged in medical practice and did not attend patients. He had therefore to provide means for continuing his experiments, and he was the more compelled to do so as he had received no assistance from the public in his studies. In France more than 1,000,000 francs (£40,000) were collected by the French nation and 200,000 francs (£8000) were given by the Government to the Pasteur Institute. On the other hand, what had been done in Germany? He would not have been able to continue his work if the Höchster Farbwerke had not supplied the necessary means, and he must confess that an inventor in Germany would risk very much if relying on the gratitude of the nation he should neglect to look after his own interests. The American public, he repeats, would benefit by the monopoly because the Höchst factory would now sell a better antitoxin and charge no more than the American chemists. An answer to this argument was published in the *Allgemeine Medicinische Centralzeitung* by a writer who declares that there was no need for Professor Behring to experiment at his own expense as there is a special State laboratory for such studies, and that his remarks about the ingratitude of his countrymen were quite uncalled for because very soon after he made his discovery he was not only appointed an ordinary professor with a fixed salary but was also left at liberty either to lecture or not to lecture entirely at his own option. With regard to tuberculin Germany had shown an enthusiasm which unfortunately was not justified by the results and in consequence the public had learned to be more reserved. According to the author of this communication Professor Behring was well provided for at the time when he applied for a patent in the United States. It will thus be seen that the controversy is rather animated.

Dum Dum Bullets.

At the last German Surgical Congress, which, as will be remembered, was held in Berlin, Professor von Bruns of Tübingen made a communication relative to the so-called Dum Dum bullets of the British army, recommending that their use should be prohibited by an international convention. It may therefore be of interest to hear the opinion of a German army medical officer, Dr. Körting, surgeon-general of the first German army corps, who has dealt fully with the question in a report on the war between Italy and Abyssinia, published in the *Deutsche Medicinische Wochenschrift*. He draws attention to the fact that whilst the Italian rifle of 6·5 millimetres calibre made small wounds and did not splinter the bones the 11-millimetre weapon of the Abyssinians caused lacerations of the muscles and comminuted fractures of the bones, Therefore the Abyssinians when wounded were not rendered incapable of fighting, and of 100 wounded about 80 could make their way to the surgeon without assistance, some of them being men with perforating wounds of the chest. Notwithstanding the very primitive dressing thousands of Abyssinians recovered within three weeks. The soldiers of the Negus very soon became aware of these facts and when arms captured from the Italians were distributed to them they did not hesitate to remove the hard mantle from the tip of the bullet. This example was then followed by the British soldiers in the Chitral campaign and it is in Dr. Körting's opinion an act of self-protection against an enemy who is not sufficiently disabled by the original projectile. Rifles having a calibre of less than 8 or 9 millimetres are incapable of effectually disabling an enemy. Dr. Körting therefore considers that there is no ground for the indignation expressed by Professor Bruns.

Treatment of Headache.

It is proved by experience that headache may sometimes be relieved by compression of the head; persons suffering from headache instinctively put their hands on their temples and feel great benefit therefrom. To make this compression more efficacious Dr. Sarason has suggested an instrument which he describes in the *Deutsche Medicinische Wochenschrift*. It consists of two plates which by a spring are firmly pressed on the temples and it looks very like a double truss. By the compression of the temporal arteries the circulation of the blood in the head is regulated and pain is relieved, especially in angiopathic hemicrania. The apparatus, which has proved useful in many cases, is termed "Migrainator" and may be had from Messrs. Schönlin and Co., Munich.

Oct. 4th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Oysters and Sewage Contamination.

BESIDES her objectionable habit of consuming oysters all the year round, allowing them no "close time," as in the British Isles, Italy has been far from careful to keep the beds in which they breed, still more the beds in which they are fattened, exempt from sewage contamination. Not a moment too soon Dr. Guido Bordoni-Uffreduzzi, Professor of Hygiene and Director of the Hygienic Laboratory in the University of Turin, has sounded a note of warning and the public has not been slow to give it due heed. Great centres of population like Milan, for example, which gets four-fifths of her large oyster-supply from the Gulf of Spezia, are filled with alarm and considering how severely the Lombard capital has been visited with typhoid fever her dread of a fresh importation of the disease through the molluscous dainty is all too intelligible. On the other hand, the oyster-breeding and oyster-vending interests are in a panic over their threatened loss of custom and have challenged the soundness of Professor Bordoni-Uffreduzzi's facts and inferences. He in turn is able to cite the evidence adduced by Dr. Cartwright Wood and Dr. Klein[1] in confirmation of his position, while the "oyster interest" replies by reference to M. J. Chatin's demonstration before the Paris Academy of Medicine[2] that "in natural sea-water the typhoid germ dies rapidly" before it can injuriously affect the oyster. True, oyster breeders, in order to fatten their wares more effectively, deposit the mollusc at river mouths in a mixture of salt and fresh water and this latter infects the oyster with the germs it has accumulated in its course. The breeders, however, assert that such practice has long been discontinued, that at Taranto and Spezia, for instance, the oysters are taken from beds placed far out at sea, away from all urban contamination, whence they are taken directly for transport to the inland towns. Both Professor Bordoni-Uffreduzzi and the breeders draw largely on British experience, and while the former urges his antagonists to adopt the procedure of their British contemporaries and to court a commission of inquiry into the whole subject, these gentlemen protest that such is their own intention and that they have nothing to fear from the most searching scrutiny into their methods. However the controversy may terminate the oyster-consuming public cannot fail to benefit. Already the oyster-baskets which used to be moored off Santa Lucia on the Neapolitan strand are protected from the sewage which gave them an evil name, the sewage being carried away in pipes to Cumae; and a similar deposit at Savona, a Ligurian seaport, *non funziona più* (is no longer in existence).

Tardy Honours to a Medical Worthy.

Lake Como reflects in its still waters few lovelier villages than Bellano, with its picturesque harbour—whence the choice abundant fruits of the Monte Grigna are exported—with its attractive edifices, its busy market-place, its thriving silk factories, and its Duomo, the *chef-d'œuvre* of Giardino Loria, dating from 1348. The place, too, has its historical, its literary, and its scientific celebrities, prominent among whom are Tommaso Grossi, the dramatist, and his yet greater predecessor, Sigismondo Boldoni, physician, philosopher, and poet as well. Born at Milan in 1597, Boldoni graduated in literature and medicine at Padua, lived for some time in Urbino and Rome, returned in 1623 to his native city, where he received an appointment in the Collegio dei Medici, and shortly thereafter was called to the University of Pavia to fill the chair of philosophy. He died at his post in 1630 the victim of epidemic disease which he had striven heroically to circumscribe. Young as he was he had made himself famous far beyond the scene of his activity. He was a brilliant lecturer and his "Orationes Academicæ" found readers throughout contemporary Europe. In poetry his chief work is his "Caduta dei Longobardi" (Fall of the Lombards), still admired and commented on. His native Bellano has now erected a bust of him in her midst and its unveiling evoked a numerous attendance of

[1] THE LANCET, Jan. 9th, 1897, p. 124.
[2] THE LANCET, March 27th, 1897, p. 922.

Digitized by Google

literary, medical, and civic notables from the chief Lombard centres. The spokesman of the occasion was Professor Mario Cermenati, who dwelt on the distinction brought to the much frequented Lake Como by the celebrities who lived or were born on its banks. From Pliny in antiquity to Alessandro Volta in the nineteenth century the Larian community never lacked illustrious representatives, among whom the "physician, philosopher, and poet" Boldoni was now if all too tardily yet worthily recognised. At the evening banquet the Senator Achille Polti once more commemorated the merits of the hero of the day and Bellano concluded the "festa inaugurale" with an effective illumination of her streets, her harbour, and her lovely lake margin.

Killed by Lightning.

Year by year the thunderstorms which accompany the transition from summer to autumn increase in violence, causing greater damage to cattle and crops and even numbering more human victims. Within the last few days the rural districts have suffered heavily from these visitations. From Palermo I hear that in the neighbourhood of Villalba a lightning stroke killed a youth seventeen years of age and severely injured two others when at work in the fields. At Amelia on the same day (the 28th ult.) a group of agricultural labourers, suddenly overtaken by torrential rainfall, fled in various directions, and one of them imprudently seeking shelter under an oak tree was almost immediately struck dead by lightning. Near Caserta the previous day a peasant was killed by a similar visitation while gathering in his crop of maize. The tale of such casualties is already an unusually long one, and taken in connexion with the abnormal frequency and violence of hailstorms and cyclones, especially in the Alta Italia, adds greatly to the interest with which preventive legislation in the shape of bills for "rimboschimento" (reafforesting) and regulating the river courses is awaited in Parliament and in the country. For if one thing is more certain than another it is that atmospheric disturbance, taking the form of torrential rainfall, thunderstorms, and cyclones, increases in the direct ratio of tree-felling without compensative replanting—a fact so impressively borne in upon the Italian public that, impatient of official delays, it has through many of its more enlightened and energetic representatives—mainly medical, I may add—organised associations "Pro Silvis" and "Pro Montibus" to conserve the forest growth and arrest the denudation of hillsides so as to obviate at their source the meteorological changes which have altered the climate of provinces and made the annual floods an ever-augmenting evil. In six weeks Parliament will reassemble, and amid the many urgent questions which clamour for serious attention and salutary solution are the hydraulic and reafforesting innovations to be proposed by the Ministers of Public Works and Agriculture respectively. Effective reform in both these directions would assuredly go far to solve the difficulties, industrial and economic, which, if unsurmounted, must perpetuate and aggravate the social malaise which breaks out in bread-riots, in brigandage, and in the thousand and one retarding causes of Italy's prosperity and peace.

A Gynæcological Tour.

At the instance of the Minister of Public Instruction (His Excellency Dr. Guido Baccelli) the professor of gynæcology, theoretical and clinical, in the Neapolitan School of Medicine (Dr. Giuseppe Spinelli) is about to start on a visit to the leading universities of Austria, Hungary, and Germany, with the special object of studying the methods there adopted in teaching obstetrics in class-room and maternity hospital. Italy, well represented in other departments of medicine, is certainly behindhand in gynæcological practice, and has much to learn in that particular from such admirably-equipped seats of learning as Vienna, Berlin, Munich, Dresden, and Leipsic. Proficiency in obstetrics, theoretical and practical, is still, I believe, an "optional" qualification on the part of her medical graduates, and it is only in exceptional instances, mainly in her chief centres of population, that the gynæcologist attains the professional standard so generally reached by his colleagues in surgery and medicine proper. To no better hands could Dr. Baccelli have entrusted the "mission of inquiry" than to those of the Neapolitan professor, whose report embodying his experiences is looked forward to with much interest, as the prelude to innovations fraught with signal benefit to the medical student and practitioner throughout the peninsula and islands.

The Medico-Military Officer in Africa.

The Dark Continent excites a weird fascination over young Italy, particularly over those of her sons who, medically trained, are gifted with tastes and aptitudes in the various fields of anthropology, climatology, and natural history. Scientific exploration already owes much to her youth so endowed and so minded, and nothing but the limited extent of her African possessions, still further curtailed by the abandonment of her "forward" equatorial policy, explains the comparative diminution in the number of her "medical paladins" witnessed of late years. Denied the coveted opportunity of such service by their own Government they seek it under the ægis of other powers and become competitors together with young French, or still more with young Belgian, graduates for posts in the exploring or political expeditions fitted out from Paris or Brussels. From Milan I hear that four of her medically qualified youths—Dr. Avezza, Dr. Caravaggi, Dr. Monti-Martini, and Dr. Paravicini—have after a severe competition been nominated "medici militari" for three years in the colonial expedition about to start from Belgium for the Congo, and it is not too much to expect that we may ere long receive from them such contributions to anthropological science and nature-study as their compatriot colleagues have already made in the latitudes south and west of Abyssinia.

Oct. 1st.

Obituary.

JOHN THOMAS NICHOLSON LIPSCOMB, M.D. ST. AND., F.R.C.S. ENG.

DR. J. T. N. LIPSCOMB, of St. Albans, whose death occurred there on Sept. 21st, belonged to a family which had been connected with the town for more than eighty years, being the eldest son of Mr. John Thomas Lipscomb, who went to St. Albans in 1815 to practise as a medical man. Mr. Lipscomb, senior, was elected alderman in 1818 and mayor in the following year. He continued to be an alderman for more than fifty years and was the first mayor under the Corporation Reform Act of 1835. Dr. Lipscomb, the subject of the present notice, was born in St. Albans in 1819, his mother being a daughter of the Rev. John Nicholson, rector of the Abbey parish church. He received his medical education at Guy's Hospital and in 1841 became qualified as M.R.C.S. Eng. and L.S.A. The same year he entered on practice in partnership with his father. In 1844 he graduated as M.D. at St. Andrews University and in 1856 he became a Fellow of the Royal College of Surgeons of England. Dr. Lipscomb continued in active practice from 1841 until about four or five years ago, when his strength became unequal to the fatigues of professional work, and for the last two years he had been in obviously failing health. Among his various appointments may be mentioned those of medical officer to the prison both before and since it was taken over by the Government, honorary consulting physician to St. Albans Hospital, and medical officer under the Factory Acts. Notwithstanding his numerous professional engagements Dr. Lipscomb took an active part in the public life of the town. He was first elected to the town council in 1855 and was the last survivor of the corporation of that date. At the expiry of the period of three years for which he was elected he withdrew from the council and did not return to it till 1869. Mr. Lipscomb, senior, was one of the four aldermen, and on his death, in September, 1869, the position was given to his son, who retained his seat on the bench of aldermen for fourteen years, only retiring in 1883. In 1870 Dr. Lipscomb was elected mayor. For forty-one years he was rector's churchwarden in connexion with the Abbey church, holding that office under three different rectors. He was also senior Justice of the Peace for the city and one of the original members of the Abbey Restoration Committee.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—A very successful bazaar was held on Sept. 27th and 28th at the Plymouth Guildhall in aid of the funds of the South Devon and East Cornwall Hospital, Plymouth. The receipts for the two days were nearly £1400.

FOREIGN UNIVERSITY INTELLIGENCE.—*Columbia University, Missouri:* Dr. Paul Kaufmann, formerly of the Cairo Medical School, has been appointed Professor of Bacteriology and Pathological Anatomy.—*Innsbruck:* Dr. Ludwig Kerschner, Extraordinary Professor of Histology and Embryology, has been granted the rank and title of Ordinary Professor.—*Gratz:* Dr. Alphons Edler von Rosthorn, of the German University of Prague, has been appointed Professor of Midwifery and Gynæcology, in succession to the late Dr. Rokitansky.—*Lemberg:* Dr. Emanuel Muchek has been appointed Professor of Ophthalmology.—*Vienna:* Dr. A. Mosetig R. von Moorhof has been appointed Extraordinary Professor of Surgery with the title of Ordinary Professor.

LITERARY INTELLIGENCE. — Messrs. William Green and Sons, publishers, of Edinburgh, announce the publication early next year of an Encyclopædia Medica by authoritative writers on the lines of their two legal encyclopædias.

COMPLIMENTARY BANQUET.—On Sept. 24th many of the colleagues and other friends of Mr. D. Edgar Flinn, M.R.C.P., F.R.C.S. Irel., D.P.H., of Kingstown, entertained him at a banquet as a mark of esteem and an expression of their pleasure on his appointment to the office of Medical Inspector to the Local Government Board, Ireland. Mr. R. L. Swan, F.R.C.S. Irel., Vice-President of the Royal College of Surgeons in Ireland, occupied the chair, and in proposing the toast of the evening, "Our Guest," stated that Mr. Flinn had all the qualifications to eminently fit him for the important post to which he had been appointed. He had been for some years a medical officer of health in England, and they all knew his thorough knowledge of sanitary science.

DEATH OF A MEDICAL PRACTITIONER THROUGH THE BITE OF AN INSECT.—On Sept. 27th Mr. George Hart, M.R.C.S.Eng., aged thirty-eight years, died at Bolton from septicæmia and septic pneumonia the results of an insect bite. He was in his usual health up to about ten days before he died, when he complained of a sharp pain near the right eye, the skin over which afterwards began to swell and a small pustule to form. Upon his return from a professional night visit he had a rigor which was followed by extensive cellulitis in the neighbourhood of the pustule and by the development of pneumonic symptoms. Septicæmia was diagnosed by his professional colleagues and confirmed by Dr. Jones, surgeon to the Manchester Royal Infirmary, and anti-streptococcic serum was resorted to, together with free incision of the affected part, but despite unremitting medical attention and the most careful nursing he succumbed. He leaves a widow but no family. Mr. Hart was a native of Bolton and had been in practice thirteen years there, and his genial, open nature had endeared him to a large circle of friends and patients, by whom his loss is very deeply felt. He studied medicine at Owens College (now Victoria University), Manchester, and qualified as M.R.C.S. Eng. in 1885.

THE LATE DR. K. N. BAHADURJI.—At a meeting of the Bombay Medical Union and of the native medical profession, which was held at Readymoney Building, Appolo Bunder, on August 27th, it was announced that from all parts of India telegrams and letters expressing deep regret for the loss sustained by the union and the medical profession throughout India had been received. The following was passed as a resolution: "This meeting desires to place on record its sincere and deep sense of sorrow at the great loss sustained by the medical profession, the public, and the country by the sudden and untimely death of Dr. K. N. Bahadurji, President of the Bombay Medical Union, and expresses its appreciation of his eminent, varied, and lasting services to the cause of medical education, reform, advancement of science, and the welfare of the profession. And it further records his zealous, devoted, and self-sacrificing work for the good of the city and in the cause of humanity during the last two plague epidemics, and resolves that a copy of this resolution, with the expression of the sympathy of this meeting, be communicated to his father, Mr. Nusserwanji Dorabji Bahadurji, by the honorary secretaries of the union."

THE MEDICAL OFFICER OF HEALTH OF BOLTON.—Dr. John E. Gould's salary as medical officer of health of Bolton has been increased to £600 and he has been at the same time relieved of the duties of public analyst. The salary formerly was £350 as medical officer of health, with £50 added for acting as public analyst.

DEATH FROM OIL OF CLOVES.—An inquest was held at Cardiff on Sept. 27th upon the body of a man, aged forty-eight years. The widow stated that he had drunk "about a quarter of a half-pint bottle" of oil of cloves, she being under the impression that it was whisky. After hearing the medical evidence the jury returned a verdict that death resulted from an overdose of oil of cloves taken by misadventure.

WEST HARTLEPOOL AMBULANCE CLASS OF THE NORTH-EASTERN RAILWAY.—On Friday, Sept. 30th, Mr. W. Gray, M.D. Edin., the lecturer to this class, was presented with a marble clock and bronzes. In the course of presenting the medallions and certificates to the members of the class Mr. Jackson, the general secretary, said that 28 candidates had passed the first year's examination, 17 the second year's examination, and 8 the third year's examination—a total of 53. During the existence of the North-Eastern Railway Centre, which was formed in 1896, 2083 candidates had passed the first year's examination, 971 the second year's examination, and 587 the final examination. There were now close upon 4000 members distributed over the system, and there were 168 properly equipped stations. The number of cases which had been attended by members was 1128 in 1896, 2451 in 1897, and 2605 for the first half of the present year.

LEEDS MEDICAL PRACTITIONERS' DINNER.—On Monday, Oct. 3rd, in the Queen's Hotel, Leeds, a representative gathering of the medical men of Leeds and the surrounding district assembled to entertain to dinner Dr. Cullingworth, who had given the introductory address at the Yorkshire College on the occasion of the opening of the winter session. The chair was occupied by Professor C. J. Wright, who was supported by the Dean of the Medical Department (Mr. Scattergood), Principal Bodington, Mr. Teale, and others. Professor Wright, who proposed the toast of the health of the guest of the evening, alluded to the esteem in which Dr. Cullingworth was held by the profession at large and to the interest with which his successful career had been watched by his old Leeds fellow-students. Dr. Cullingworth, in replying, expressed his sense of honour in being called to visit his old school and showed his warm attachment to it. He referred in eulogistic terms to the work of Dr. Hardwicke, to whose example and influence much of his success was due. In conclusion Dr. Cullingworth proposed "Success to the Medical Department of the Yorkshire College." The toast was responded to by Dr. Wardrop Griffith.

LEEDS INFECTIOUS HOSPITALS AT MANSTON.—Accompanied by the Lady Mayoress, the Lord Mayor of Leeds opened on Saturday, Oct. 1st, the infectious diseases hospitals which have been erected by the corporation on their Manston estate at a cost of some £40,000. The hospital buildings cover an extent of 100 acres. The chairman of the Hospitals Committee, after the reception of the Lord Mayor, said the want of accommodation had undoubtedly been acutely felt by the wage-earning classes in Leeds. For many years Leeds had been content to possess some 100 to 120 beds for infectious diseases, which represented roughly about one bed for every 3000 inhabitants. It had been laid down more or less as a rule that industrial centres like Leeds should have not less than one bed per 1000 of the population. This would mean that Leeds should have 400 beds for the present estimated population. The accommodation now provided, with the accommodation already available at the Beckett-street Hospital, would bring the total number of beds available up to 194, or some 200 less than the accommodation actually required. The Lord Mayor said the city was to be congratulated on the completion of such excellent buildings as those in which they were assembled. The study of the history of infectious disease clearly proved that it was rifest where men were most crowded and where fresh air failed to penetrate. Knowledge which had been gained by painful experience was now being used for the benefit of our large cities, but could be hindered by ignorance, carelessness, and dirt.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

ADENOIDS AND LARYNGISMUS.

MR. LENNOX BROWNE, referring to the account of a case of laryngeal stridor published in THE LANCET of August 27th (p. 552), writes to us to state that so long ago as Feb. 15th, 1890, he expressed in the columns of the *British Medical Journal* "a tolerably sure conviction that in almost every case of laryngismus, as well as in those of tetany and convulsions, the subject would be found to be a mouth-breather and that if sought for adenoid growths would always be discovered."

WHAT IS A *BONÂ-FIDE* STUDENT?

To the Editors of THE LANCET.

SIRS,—A gentleman whom I have for some time employed as dispenser and bookkeeper, and who has sat two or three times for the final examination of the triple qualification without complete success, has now passed in midwifery and is exempted from appearing in that subject again. I should like to ask you your opinion, taking into consideration the recent resolution of the General Medical Council, whether I am justified in allowing him to attend midwifery cases under my supervision. He is an excellent accoucheur and could be very useful in this capacity while he is preparing himself for examination in the remaining subjects of the final. In the notice from the General Medical Council to general practitioners forbidding the use of unqualified assistants there is a clause which appears to me to countenance the use of *bond-fide* medical students in this respect, but I should like my opinion confirmed. I am, Sirs, yours faithfully,

Oct. 4th, 1898. L.R.C.P.

*** We doubt if the employé in question is the sort of student contemplated by the General Medical Council and think that to allow him to attend cases of midwifery might subject "L.R.C.P." to censure.—ED. L.

A QUESTION OF DIAGNOSIS.

To the Editors of THE LANCET.

SIRS,—Three days ago I was called to see a woman, aged thirty-six years, whom I had been attending for some time for various minor ailments, chiefly dyspepsia. On my arrival I found her in bed, having been lifted therein after a fall. She had been attending to her household duties as usual and was just about to cut some bread when suddenly without a moment's warning she fell to the ground. I found her speechless and with the right arm and leg paralysed. She was not unconscious nor was there loss of sensation on the paralysed side. The tongue pointed to the paralysed side. Taking all the facts of the case into consideration, and especially as I found on examining the heart that there was mitral stenosis, I made a diagnosis of embolism. The friends expressed a desire to have a second opinion, and accordingly a colleague was called in, a man of many years' experience (I am myself only a little more than two years qualified). He disagreed with the diagnosis of embolism and suggested that the condition was one of "congestion of the brain due to biliousness" (these are his exact words). I should say th the day before the stroke the patient had had an

Digitized by Google

attack of vomiting and diarrhœa. But I never in my student days heard of hemiplegia and aphasia brought on in such a way nor can I find any reference to such a case in any books at my command, I should therefore be very grateful if you or any of your readers would tell me if such a thing has ever occurred in their experience or if it is possible. I may say that there has not yet been the slightest improvement in the patient's condition as regards the paralysis although I have acted on my colleague's suggestion and treated the "biliousness."

I am, Sirs, yours faithfully,

Sept. 28th, 1898. DUBITANS.

P.S.—Of course, I am not asking you to decide between my colleague and myself nor shall I make any use of any opinions I may receive. I merely seek for information for my future guidance.

'FUCUS VESICULOSUS."

IN reference to the letter of "Enquirer," published in THE LANCET of Oct. 1st, page 906, Messrs. Parke, Davis, and Co., of 451, Oxford-street, write to us that they sell large quantities of it and receive favourable accounts from those who use it. They will be glad to reply to any communication which "Enquirer" may make of them, either personally or by letter, and they enclose us a small brochure on the seaweed in question. M. Duchesne-Duparc is said to have been the first to recommend it as a means of reducing obesity. According to him the remedy is best taken in the morning fasting, and its use requires no change in the ordinary diet; much farinaceous food, beer, prolonged baths, and sedentary habits should, however, be avoided. Dr. Griffith, author of "Corpulence, or How to Get Lean," describes his personal experience of the treatment in the *Baltimore American* (New Preparations, 1878). A patient under his care who had been drinking an infusion with the expectation that it would cure psoriasis informed him that it had done no good, but that it had diminished his fat quite considerably. Dr. Griffith then himself commenced drinking an infusion of it. He says: "In the course of a few weeks my burdensome form grew 'small by degrees and beautifully less,' much to my satisfaction. ..... I administered it to three of my corpulent neighbours with the following results. In neither of the cases was it administered with any regard to regularity. In one case the loss was from 12 lb. to 15 lb. in about two months; in another the diminution in weight was 30 lb. in three months; in the third case there was decided relief from the discomfort under which the patient laboured."

"THE PATHOLOGY OF HERPES ZOSTER: 'ABERRANT VESICLES.'"

To the Editors of THE LANCET.

SIRS,—In an annotation in THE LANCET of Sept. 24th it is said, in discussing the prevalence of "aberrant vesicles," "for these vesicles have never been observed, as far as we know, in this country." My colleague, Dr. W. A. Mackay, described such in a paper entitled "An Unusual Case of Zona," which was published in the *Glasgow Medical Journal* for October, 1897.

I am, Sirs, yours faithfully,

ALEX. JOHNSTON.

City of Glasgow Fever Hospital, Sept. 27th, 1898.

"POISONOUS SHRIMP PASTE."

To the Editors of THE LANCET.

SIRS,—It would be interesting to know the precise history of the preparation of the shrimps which when consumed at St. Anne's-on-the-Sea produced symptoms of acute poisoning. Some years ago, when holding a dispensary appointment in Liverpool, I happened one day to be shown into a ground-floor room of the most filthy description, where a dirty old Irishwoman was busily engaged in peeling shrimps. It was a hot summer day and her hands looked as if they had not been washed for months. I asked her whether she was peeling the shrimps for her own consumption or for others and was told that she did it for her living. "What becomes of them then?" I asked, and was informed that they were potted and sold in Southport. Then I remembered having noticed in the windows of various restaurants in that town tempting-looking white pots containing shrimps embedded in butter which I had innocently supposed to have been a native product prepared on the premises. I have never eaten potted shrimps since that day.

I am, Sirs, yours faithfully,

Clifton, Sept. 30th, 1898. C. J. WHITBY, M.D. Cantab.

URÆMIA.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 4th, 1898, an article was published on the Prognosis and Treatment of Uræmic Convulsions, with notes of two cases. My attention has been drawn to the first case, viz., that of a Derbyshire clergyman, and I am disposed to question the diagnosis of uræmia. In my opinion the history of the case—the facial congestion, the stertorous breathing, the high tension pulse, the hypertrophied heart, and the coma—all point to one cause—viz., increased vascular tension, an overfilled and rigid system putting an extra strain upon those vessels which anatomically are least able to withstand the same. The patient being of plethoric habit it is possible that an excess of urea or uric acid in the blood would predispose to increased arterial tension. In such a manner also would the active physical habits, and in other cases the gouty habits, the absorption of lead, the use of alcohol, and such like factor induce cardiac hypertrophy and arterial rigidity; but they are but factors, and in the above case the history of an active physical life is as important as the history of a healthy appetite, and taken together in his case with possible other factors unknown or non-stated (such as the use of alcohol), tend to produce the same condition—viz.: arterial degeneration. As regards the urine only the faintest trace of albumin was detected, the specific gravity was 1030 and there was a free deposit of urates. Now, from the point of view of failure of renal function it appears, on the contrary, from the scanty evidence produced that the kidneys were healthy and were discharging both water and urea freely. By the fact that there was no albumin found in the urine—the evidence is in favour of a normal secretion by the tubes. Moreover the treatment showed that as soon as the vascular tension was relieved by active purgation the patient regained consciousness, recovered, and lived for two years, whereas in uræmia a patient may suffer from profuse diarrhœa for several days previously to death, the blood and tissues being loaded with urea, and in nowise influence the ultimate result; and should the condition of the kidneys by disease be accountable for so serious a condition of coma by retention of urea in the blood, the fact that there is little or no evidence of such disease so detected by examination of the urine is hard to explain away. And the term "uræmia" has been associated hitherto with a definite renal lesion, whereby the accumulation of urea in the blood and tissues is due to faulty elimination by the tubal epithelium and acting on centres either directly or indirectly by peripheral stimulation. To sum up, Was the coma due to toxæmia (such as uræmia) or to cerebral hæmorrhage?

I am, Sirs, yours faithfully,

A. P. WALTERS, M.R.C.S. Eng.

Tilt Cove, Newfoundland, Sept. 13th, 1898.

*** We have omitted the re-statement of the case made by our correspondent, as the original paper (The Prognosis and Treatment of Uræmic Convulsions and Coma, with Special Reference to the Senile Kidney, by Arthur T. Wilkinson, B.A., B.Sc., M.D. Lond.) will be found in THE LANCET of June 4th, 1898, page 1524.—ED. L.

"WANTED DIAGNOSIS AND TREATMENT."

To the Editors of THE LANCET.

SIRS,—In reply to the letter under the above heading signed "L. M." in THE LANCET of Sept. 24th I beg to say that the diagnosis is "gouty migraine." If "L.M." will read my paper headed "On Migraine" in THE LANCET of Jan. 14th, 1893, p. 79, he will find the puzzle explained. Three weeks at Harrogate will probably set him up for the next six months, if not for a longer period.

I am, Sirs, yours faithfully,

Colchester, Sept. 26th. ALEXANDER WALLACE.

To the Editors of THE LANCET.

SIRS,—The gouty headache that "L. M." complains of would probably be controlled by the following treatment: complete absence of alcohol and butcher's meat from the diet and 5 gr. of salicylate of soda one hour after meals. Let him take a Turkish bath two days before the paroxysm is due.

I am, Sirs, your faithfully,

Oct. 2nd, 1898. F. N.

"THE MEDICAL DIRECTORY."

To the Editors of THE LANCET.

SIRS,—In reply to the letter of the publishers of the "Medical Directory" in THE LANCET of Oct. 1st will you permit me to say that it is no doubt true that Parliament has for administrative convenience caused certain statutes to apply to Monmouthshire as well as to Wales? These statutes are, however, exceptional in character and insignificant in number and in every instance Monmouthshire is specifically named—an indication that Parliament has not considered Monmouthshire to be a part of Wales. On the other hand, in general statutes applying to Wales alone—the Sunday Closing Act for Wales, for example—Monmouthshire is never included in the area affected by the Acts. Messrs. Churchill practically give their case away in adducing the example of the Cardiff College, for, as they correctly state, the title of the College is "The University College of South Wales and Monmouthshire," an indication, if any were needed, that Monmouthshire is not a part of South Wales, and no one, I suppose, would consider it a county of North Wales. Will you, of your courtesy, allow me to make a last appeal to them? If they be determined to retain a Wales section in the Directory will they follow the example to which they appeal and entitle that section "Wales and Monmouthshire"? If they will, then we Monmouthshire men will have little cause to complain.

I am, Sirs, yours faithfully,

A MONMOUTHSHIRE SUBSCRIBER OF THIRTY

Oct. 1st, 1898. YEARS' STANDING.

To the Editors of THE LANCET.

SIRS,—Of the various references required to be made to the Medical Directory two only are of sufficient importance to be considered seriously in any re-arrangement. These are (1) the location of a medical man being unknown, the desire to find it, and (2) the location being known, the desire to know all about him, as, for instance, his address, qualifications, &c. After mature reflection I have come to the conclusion that both these requirements would be met,

Digitized by Google

with less loss of time and money, by the adoption of the following arrangement than is the case under existing conditions. I suggest (1) that all the names now sectionally separated be alphabetically arranged under one general list of British (and Irish) qualified medical men. (2) That a capital letter be placed in the margin opposite each name, sufficiently prominent to catch the eye, suggesting the location of each, as follows: L, E, W, S, I, F, N, and M, representing London (postal district), England (provincial, including Monmouthshire), Wales, Scotland, Ireland, Foreign (practitioners resident abroad), Naval, and Military. This would obviate the objection which might be raised against having to search through a long list of names where the location is known; all letters except the one denoting the locality required would be passed over. (3) That the local lists be converted into one general localised list, excepting the London street list, which would be more convenient to be kept separated. (4) That the universities, colleges, and medical schools be placed under the heading "Medical Education." It appears to me that under this re-arrangement the book itself would be less cumbersome, and much labour would be saved to those who are engaged in preparing it. It would certainly be more convenient to the profession at large.

I am, Sirs, faithfully yours,

A SUBSCRIBER OF TWENTY-FIVE YEARS' STANDING.

Oct. 3rd, 1898.

A POINT IN MEDICAL EVIDENCE AT CORONERS' INQUESTS.

To the Editors of THE LANCET.

SIRS,—I was called out one night at 11.35 to see a man who was said to be dead; I went and found that he was dead. It seems that before they came for me they had sent for another medical man, who had attended the man a month before for some affection of the heart. Two days after my visit to the man a coroner's officer called to say that the other medical man was to attend at the inquest. I should like to know what your view of the matter is.

I am, Sirs, yours faithfully,

Oct. 3rd, 1898. R. M. R.

*** It is not necessary that the last medical man who saw the dead body should give evidence at the inquest, for it often happens that he is not the regular medical attendant whose evidence may be required to explain the death.—ED. L.

BARKOO-ROT?

To the Editors of THE LANCET.

SIRS,—Could you or any of your correspondents give me any information as to a disease called in Western Australia "barkoo-rot," and also the best remedy for the same? It is apparently a skin disease affecting the hands of miners who use instruments made of a certain kind of wood.

I am, Sirs, yours faithfully,

Sept. 28th, 1898. Z.

INCORRECT MEDICAL CERTIFICATES.

To the Editors of THE LANCET.

SIRS,—From time to time we read in the daily papers of medical men giving certificates of inability of patients through sickness to attend as witnesses in the law courts, and later in the day such witnesses calmly walking into the court, thus proving the medical man either to be a fool or a liar. A case in point is that concerning a jury list related in the *Daily Telegraph* of Sept. 28th. A gentleman attended and claimed to be taken off because he was deaf. Hitherto his name had been taken off, he said, on his sending a medical certificate. On examination, however, the chairman found that he was not deaf and the story ends by saying that he was retained on the list. I think, Sirs, that the name and address of these blackguards who will write a false certificate for a fee of 2*s.* 6*d.* should be posted up at the end of THE LANCET every week with an editorial remark. Will the daily papers please copy?

I am, Sirs, yours faithfully,

St. Day, Cornwall, Sept. 29th, 1898. E. H. WORTH, M.R.C.S. Eng.

*** In our experience such cases are but seldom heard of. Nor does the "case in point" impress us much. For if a wily citizen called on a medical man and said he was deaf, and if it appeared from ordinary tests that he could not hear, it would be the duty of the medical man to give a certificate to that effect. We do not see any evidence that the medical man knew that an imposition was being attempted or that he sold his signature from corrupt motives.—ED. L.

WEIR-MITCHELL TREATMENT.

To the Editors of THE LANCET.

SIRS,—Will one of your correspondents kindly inform me of the address of a private institution where a lady patient may undergo the Weir-Mitchell method of treatment for neurasthenia or chronic neuralgia?

I am, Sirs, yours faithfully,

Oct. 3rd, 1898. W.

THE CLIMATE OF UGANDA.

To the Editors of THE LANCET.

SIRS,—I want information on the climate of Uganda—its temperature and statistics as to fever and death-rate among Europeans. Can any of your readers help me in the matter?

I am, Sirs, yours faithfully,

Oct. 3rd, 1898. ASHBY.

POLARITE.

To the Editors of THE LANCET.

SIRS,—(1) Is polarite a reliable filtering medium? (2) If it does not act as a filter what is its action in the purification of water, if any?

I am, Sirs, yours faithfully,

Christchurch, Hants, Sept. 29th, 1898. R. LLOYD LEGATE.

PRURITUS ANI.

To the Editors of THE LANCET.

SIRS,—In reading a report of one of the medical societies lately which was reported briefly in THE LANCET I noticed that the subject of pruritus ani was touched upon by several of the speakers and the statement was made by Mr. Allingham that in 50 per cent. of the cases where no obvious cause was found an acrid rectal secretion would account for its etiology. I have been a sufferer from the complaint for many years and am confident that the condition named is the cause o it. I have tried innumerable remedies with little or no benefit. My object in writing to you is to ask if Mr. Allingham or some other competent authority will be good enough to state their views as to the appropriate treatment for the conditions above mentioned. Theoretically, a weak carbolic or astringent injection seems indicated, but I shall esteem it a favour if an opinion would be given on the subject.

I am, Sirs, yours faithfully,

August 20th, 1898. A TWENTY YEARS' SUBSCRIBER.

THE NEW PHARMACOPŒIA.

THE British Pharmacopœia of 1898 is having as favourable a reception as it well could have had. The sales of it up to Sept. 22nd were 18,220.

Bijou can obtain full information from her medical attendant.

Mr. J. O. Neumann.—We cannot notice an instrument which we have had no opportunity of testing or seeing at work.

Cantab. should apply to the dean of some medical school for a tutor but we are not quite sure whether he could get signed up by private teaching. He might also consult the list of medical teachers on page 657 of the Students' Number of THE LANCET.

Subscriber.—Inasmuch as the dentist in question is not registered in this country he must be looked upon as an unregistered practitioner. The administration of an anæsthetic by a medical man for an unqualified dental practitioner is to be regarded as an act of unprofessional conduct.

Microbe will find a full account of the Exeter septic tank system in "Purification of Sewage and Water" (Sanitary Publishing Company, Limited, 5, Fetter-lane), by Mr. W. J. Dibdin. Mr. C. G. Moor has also written a small pamphlet on the subject which is published by Mr. W. H. Hewlett, Wivenhoe.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address

ON

VARIX: ITS CAUSES AND TREATMENT, WITH ESPECIAL REFERENCE TO THROMBOSIS.

Delivered on Oct. 6th at the Inaugural Meeting of the Nottingham Medico-Chirurgical Society, Session 1898-99,

By WILLIAM H. BENNETT, F.R.C.S. Eng.,

SURGEON TO ST. GEORGE'S HOSPITAL; MEMBER OF THE COURT OF EXAMINERS, ROYAL COLLEGE OF SURGEONS OF ENGLAND; EXAMINER IN SURGERY IN THE UNIVERSITY OF CAMBRIDGE, ETC.

MR. PRESIDENT AND GENTLEMEN,—The difficulties which present themselves to one called upon to give an address upon an occasion like this are of necessity considerable, not the least of them being that involved in the choice of a suitable subject. It is my good fortune in the present instance to have been entirely relieved of anxiety in this respect by the kindness of your secretary, Dr. Kingdon, who has been good enough to intimate that some matters relating to varicose veins might form an acceptable topic. I am grateful for this help, not merely because it has relieved me to some extent of the responsibility of choosing a subject, but because it enables me to deal with a common and, in the minds of some, I fancy, unimportant surgical complaint, to which, if the selection of a subject had been left altogether in my hands, I fear I should have had some hesitation in asking the attention of such an audience as this. Surgery at the present time deals with so much that is great in its conception and performance that there is a danger of the minor and more common matters being somewhat neglected and, indeed, sometimes of being almost overlooked—a most unfortunate tendency, paricularly from the educational standpoint. The observations which I am about to make must, I fear, be more or less of the nature of an epitome only, since the time at my disposal will not allow of more than that. I do not know that I have anything actually new to bring forward for your consideration; nevertheless, I venture to hope that the views which I shall express, since they differ to some extent perhaps from those commonly held, may be at least of sufficient interest to justify the trespass I am making upon your time. For obvious reasons I shall confine myself for the most part to varix of the lower limbs; I do not propose to weary you with statistics, but I must claim your indulgence when, in order to make my position clear, I have to refer to certain elementary details which must be familiar to all.

The Causes of Varix.

The origin of varicose veins has until comparatively recently been generally considered to be something of a mystery; speculations as to their causation have from time to time been made, but nothing very definite with regard to the cases commonly met with has been forthcoming. In some lectures published in 1889 [1] I arrived at certain deductions based upon the consideration of a large number of cases; increased experience during the past ten years has led me to form more positive conclusions than were quite justifiable at the time I have mentioned. A distinguished surgeon, lately deceased, who was himself a sufferer, in the course of a conversation not long ago went so far as to say that he did not believe that anything whatever was known about the origin of varix, and, further, that very little more was known about its proper treatment; and it must be admitted that the information obtainable from the ordinary sources is very meagre. I venture to think that a little consideration will show that the causes of the disease are not so obscure as to be, at all events in the majority of cases, insusceptible of explanation. For practical purposes, so far as their causation is concerned, varicose veins may be divided into four classes: (1) those which are congenital; (2) those due to obstruction of blood-current; (3) those caused by strain without thrombosis (traumatic); and (4) those the result of thrombosis.

1. The congenital cases form a large percentage of those usually met with and consist of two varieties: (*a*) those connected with the subcutaneous veins only, and (*b*) those having a direct and gross communication with the deep venous trunks. The second of these varieties is, for reasons presently to be mentioned, by far the more important. As an example of the first variety, the local mass of varix often seen in the calf of the leg may be mentioned, and of the second kind the convoluted collection of varicose veins about the inner side of the knee, which, turning towards the middle of the popliteal region, ends in a large vessel which joins the deep vein directly by passing through the normal opening in the fascia over the popliteal space. A third variety of congenital varix is that in which the whole venous apparatus of a limb is over developed with or without corresponding increase in size of the main artery. Such cases vary in degree from what is nothing more than a little exaggeration in the size of the vessels to a morbid condition which may, without inaccuracy, be termed diffuse nævus. Congenital varix is sometimes very extensive. A patient who occasionally comes to see me at St. George's Hospital has the most exaggerated varix of all the superficial veins of the right side of the body with which I have met, some of the vessels on the chest being of enormous size. He is now about forty years of age, very strong and entirely free, so far as our means of examination allow one to judge, from any visceral abnormality; there is a large varicocele, but there are no piles. The condition, he is certain, has existed since childhood, and he says that his father was similarly affected. The congenital cases are, as a rule, not noticed until about or after the time of puberty, when a rapid increase of the abnormality often occurs. In connexion with these congenital cases the question of the influence of heredity naturally arises. So far as I can judge heredity is a considerable factor (mainly on the father's side), although I am prepared to admit that the decision upon this point must be difficult in a complaint so common. Nevertheless, when it is possible, as is not infrequently the case, to trace the same form of varicosity through successive generations, and in several members of the same family at the same time, it is difficult to conclude otherwise than that in a large number of cases at least heredity is a strong influence.

2. Cases due to obstruction of the blood-current by external or internal pressure. The most familiar examples of this type are afforded by the varix resulting from pressure of the gravid uterus in successive pregnancies in some women and by the varicosity produced in the veins at a lower level by the pressure of tumours above. In such cases, if the pressure is sufficiently transient and not too complete, the whole of the dilatation may subside permanently upon the removal of the pressure; if, however, the tension in the veins is enough to cause the valves to give way, or if, as may happen, aseptic thrombus forms immediately below the seat of pressure, permanent varicosity results. The gradual increase in varix which occurs after successive pregnancies is, I believe, to be explained upon one of these hypotheses, the occurrence of aseptic thrombus being, in my judgment, more common than is generally thought.

3. Cases caused by strain. There is, I believe, no doubt that, *cæteris paribus*, the veins of persons who when young are subjected to abnormal, and especially sudden, strain, such as may occur in hard "training," in gymnastics, particularly the lifting of heavy weights, or in any violent exercise, as, for example, heavy football playing, tend to become varicose more than the veins of persons whose occupations or amusements throw less strain upon the vascular apparatus. The greater the strain in proportion to the strength of the individual the greater will be the tendency to the development of varicosity. The most exaggerated varicosity arising in this way that I have seen was in an enthusiastic football player in whose ancestors there were no traces whatever of a similar condition; in his case no sign of the defect showed itself until a distinct feeling of something having "given way" in the thigh had occurred on two or three different occasions, after which first mere enlargement and then tortuosity of the long saphena and its tributaries followed. After careful observation I have formed the opinion that the immediate cause of the development of varicosity in cases of this kind is the giving way of the vein valves, usually the proximal pair, which under condition of great general tension naturally have to bear the greatest pressure, although they are not unfrequently imperfect

[1] Clinical Lecture on Varicose Veins.

Digitized by Google

anatomically. To produce proof of this contention is necessarily difficult, but the evidence of a case like the following is undeniable.

A young man, aged eighteen years, of strong physique and in perfect health, whilst doing some heavy gymnastic work felt something "give way" in the upper part of the right thigh. No discomfort worth mentioning followed, but as he felt some weakness about the part he consulted me three weeks afterwards. Upon examination the saphena from the groin to a point just above the knee was at least twice the size of the vein below that point, which was apparently normal; the enlargement above ceased abruptly at the point named. The veins in the opposite limb were normal. There could be no doubt that the proximal saphenal valves had become incompetent by reason of the strain and that the vessel had become enlarged in consequence down to the next competent valves. Circumstances, apparently unavoidable, made it necessary for the violent exercise to be continued, and a second strain was distinctly felt a fortnight after I saw the patient. A month after the second strain the whole saphena from the groin to the ankle was very large, later it became tortuous, assuming all the characters of ordinary varix.

I have seen other cases of the same kind. In one of these I removed a considerable length of the saphena, which was as large as my index finger; the valves, of which there were three pairs in the portion removed, were incompetent and one flap had been apparently torn almost off the vein wall, so that it must have been floating nearly free in the blood stream. In connexion with this last remark it is noteworthy that in some cases of varix arising in this way from sudden strain *a soft bruit* is perceptible upon auscultation, although no pressure of any kind is made upon the vein; indeed, it may be possible to hear the bruit by placing the stethoscope on a limb a short distance from the affected vessel. Included in the category of varix arising from strain are those cases of varicose veins in the lower limbs occurring in persons whose occupations entail long-continued standing without much variation in position—girls and young men serving in shops, for example. In these cases the strain is, of course, very slight, but it is so continuously applied by the long column of blood in the saphena that the ultimate effect is to produce varicocity of various degrees in different subjects. There is, however, sufficient reasons for believing that varix of this kind occurs only in subjects whose veins are in some way defective, congenitally, from previous traumatism, or from pathological change.

Some years ago I had an opportunity of ascertaining the condition in relation to varix of the lower limbs in a number of persons selected at random who were employed in a large business house. 15 per cent. were grossly affected and of these nearly half were very robust; on the other hand, amongst those free from the defect were some of the most anæmic and delicate looking of the number examined. Bearing in mind that the occupation of all these subjects was identical and that the defect was not confined to the weak but occurred with apparent indifference in the strong and weakly, it must, I submit, be conceded that there is here strong presumptive evidence in cases of this kind that the origin of the disease lies in some inherent defect in the veins themselves. The fact that the condition when once started tends to become more exaggerated in weakly subjects in no sense affects the validity of this contention.

4. Thrombosis as a cause of varix. The effect of thrombosis of the large venous trunks, such, for example, as the iliac vein or inferior vena cava, especially as a complication of enteric fever, in the production of general varicosity of the limb below is too familiar to call for comment. The importance, however, of thrombosis as a factor in the causation of a certain type of varicosity in the leg is not, I venture to think, commonly recognised, nor am I aware of any mention of the matter in surgical literature. Strains and other similar injuries of the leg or ankle followed by pain and acute tenderness down the middle of the calf, sometimes insufficient to cause more than momentary or very transient trouble, but at times enough to render the limb practically useless for a considerable period, are not infrequently followed very soon by dilatation of the saphena veins, which, if more than very temporary, passes subsequently onwards to tortuosity, with the development of characteristic varix which rarely extends above the knee, terminating generally at the point at which the great saphena of the thigh is completed by the junction of the two trunks at the upper end of the leg. The cause of this development is thrombosis of the main deep veins—i.e., the venæ comites of the posterior tibial artery, &c. The primary saphenal dilatation is merely the result of the establishment of the collateral circulation. If the thrombus clears up or if the unaffected deep veins take up the collateral function this dilatation is temporary only and soon disappears; if, on the other hand, as not infrequently happens, the thrombus leads to occlusion of the deep channels, the superficial dilatation remains permanently and sooner or later a state of ordinary acquired varicosity of the leg follows, which extends, as a rule, no higher than the junction of the two branches already mentioned, which complete the formation of the femoral saphena, as at this point the blood current becomes so free that no appreciable change is produced higher up. The clinical importance of these cases is considerable and lies rather in the history of the cases than in the local symptoms. A proper appreciation of the condition is essential in relation to treatment, as I shall presently show.

A characteristic case of this kind is the following. A man, aged thirty-six years, whilst walking slipped off the kerb and "sprained his ankle"; he paid no attention to the injury at the time. On the following morning on attempting to leave his bed he felt so much pain in the calf of the leg that he could not do so. I saw him a day later—i.e., about 48 hours after the accident; he was then suffering acute pain on the least movement in the middle of the calf; there was tenderness as well as other unmistakeable symptoms of deep thrombosis. Just behind and below the internal malleolus there was slight puffiness; over this area some bruising appeared a few days later. In three weeks he was well enough to get about, but the superficial veins of the leg were full and considerably larger than those on the opposite side. I saw nothing more of the patient for two years, when he again came to see me giving the following account of himself. Although he had apparently recovered from the injury and could do practically anything he desired in the way of exercise he had experienced at times after a heavy day's work a feeling of fatigue in the affected leg, and a year before seeing me he observed that the veins about the leg were much swollen. By degrees this swelling increased until it became so marked that he felt bound to seek advice. Upon examination I found well-marked varicose veins of the leg of the kind I have mentioned and about the inner ankle was a pad of small dilated vessels. The whole leg was slightly larger than its fellow, but there was no tenderness, œdema, or other unnatural manifestation. The thigh was precisely as that of the opposite side.

In the course of some investigations as to the condition of the deep veins on the cadaver in persons who showed obvious signs of varicose veins in the leg I found in two cases the venæ comites of the posterior tibial artery completely occluded by organised thrombus. At the time (now some ten years ago) I attached no importance to the condition, but in the light of subsequent clinical experience it is of distinct significance in relation to the point I am discussing.

THROMBOSIS IN VARIX.

It is commonly stated that varicose veins of the lower limbs are not in any way dangerous to life although they may be productive of discomforts and complications sufficiently serious to incapacitate a patient from following any active employment. Speaking generally this statement is without doubt true, but there are exceptions to it of enough importance to make the matter worthy of some consideration. There are certain well-defined types of varicosity which certainly afford an ever-present source of danger which, if the condition be recognised, is easily obviated by the removal by operation of the veins concerned. That the existence of this danger is not recognised by some practitioners is abundantly clear from the obstacles which even now are often thrown in the way of operations which, being practically devoid of risk, are suggested as a preventive measure before local changes have occurred which rapidly tend to disastrous results. In the course of a comparatively short time I have seen 1 case in which life was sacrificed and 7 others in which it was placed in jeopardy by the failure to recognise the importance of certain conditions to which I shall presently refer. For practical purposes the only immediate dangers to life arising from varicose veins are: (1) the occurrence of profuse bleeding from the "bursting" of a thinned vein; and (2) the formation of thrombus which may either rapidly extend to the great venous channels or lead to the detachment

Digitized by Google

of emboli, which if large enough may cause immediate death, or if they pass through the heart lodge in the lungs, giving rise to pulmonary lesions which are sometimes fatal.

It is, I believe I am right in saying, a rather common belief—which is in a general way justifiable—that thrombosis of a vein which is varicose is of less importance than of a vein which is normal, since extension of the clot or its disturbance in the former condition is less likely to happen. Indeed, it is a common experience to find patients allowed to get about and follow their ordinary vocations with comparatively recent clots in varicose veins of the leg, which if they existed in veins which were not varicose would inevitably lead to the prescription of long-continued complete rest. There is no doubt that so far as the limb below the knee is concerned, in the absence of very gross neglect, results serious to life rarely follow immediately from thrombus in varix. In the thigh and at the knee, however, the matter is altogether different since a recent clot in varicose veins in those regions is always a serious and sometimes a fatal lesion; in certain types of varix the gravity of thrombus cannot be over-estimated. The local conditions predisposing to thrombosis in varix are—(*a*) cysts or acute bends in greatly dilated vessels; (*b*) peculiarity of situation with regard to mobility; and (*c*) liability to injury. Now traumatic thrombus in varix almost invariably begins either in cysts, cystic dilatations, or in the acute bends of very tortuous and greatly dilated vessels. In situations in which the affected veins, especially if very large, are continually subject to mobility—e.g., alternate bending and straightening—thrombus is prone to form. The effect of traumatism as a cause of thrombosis is too familiar to require comment. The tendency of thrombosis in varix to spread and invade the great deep venous channels increases with the size of the vein, the absence or inadequacy of the vein valves, and especially with the existence of a gross lateral communication between the part in which the clotting occurs and the main deep venous channel nearest in relation to it. The liability to embolism will of necessity be increased by the same conditions; upon these conditions, therefore, may be said to depend the gravity of thrombosis in varix. Of the constitutional states predisposing to thrombosis it is unnecessary to speak; they act in the same way, but with more force, in varix as they do under normal local conditions.

THE DANGEROUS REGION IN VARIX.

If a portion of the inner half of the circumference of the lower limb be marked off by two transverse lines one about the middle of the thigh and another three inches below the line of the knee-joint—i.e., at the point where the two main subcutaneous veins of the inner side of the leg join to form the main femoral trunk of the internal saphena—an area will be included in which the local conditions predisposing to thrombosis in varix are present in a remarkable degree; indeed, for practical purposes they may be said to be limited to that area. Cysts, often of great size, are there common; huge dilated tortuous vessels, valveless and with abrupt bends, are frequent, and are constantly being subjected to the straining movements produced by flexion and extension at the knee. The special liability to injury of the affected vessels about the inner side of the thigh and knee in riding and numberless other amusements and occupations is obvious. So far as my experience goes all cases of thrombosis in varix of a grave nature, apart of course from those dependent upon acute inflammation or other septic conditions about the limb, with hardly any exceptions originate within the limits of the area described. I have therefore been in the habit of designating it the "dangerous region of varix," employing the term "dangerous" to imply risk either to life or to the integrity of the limb. In order that the importance of the dangerous region may be fully understood it is necessary to briefly indicate the several varieties of varix which are found within its limits. Excluding slight tortuosities of unimportant venous radicles there are eight distinct varieties of varix met with in this region; all are either connected with or actually involve the long saphena.

1. An extensive arrangement of tortuous and dilated veins, containing many small cystic dilatations, which commences at the outer side of the knee and running upwards and inwards just above the patella, joins the saphena a little below the middle of the thigh. This varix is often joined at its commencement, where there is also sometimes a deep branch connecting it with the deep veins, by an afferent tortuous vessel proceeding across the front of the leg or knee from the saphena below or opposite the latter point.

2. A large mass of varix above and to the inner side of the knee, sometimes extending down into the upper part of the leg; the mass is quite superficial, attached above to the saphena, upon which it lies and conceals. It has running into its lower end large superficial varicose veins, beneath which the saphena of about the normal size can usually be seen to run.

3. Two, three, or more distinct venous cysts, varying in size from that of a horsebean to a large cherry, connected to one another by intervening tortuous and dilated veins. This arrangement generally extends from a little below the middle of the thigh and reaches to the level of or below the line of the knee-joint; it is quite superficial, overlying the saphena, to which it is attached above; below it receives varicose veins from the leg.

4. A mass of varicose veins turning round the inner side of the knee connected with the saphena either above or below and ending nearly always by direct communication over the middle of the popliteal space, either with the popliteal vein itself or with the short saphena immediately before it joins the deep vessel.

In these four types the saphena, although it may in exceptional cases be large and tortuous, is, as a rule, normal.

5. A similar condition to that described in Variety 1, but as a rule smaller. It terminates above in a considerable cystic dilatation of the saphena just below the middle of the thigh and receives below varicose veins from the leg. The saphena itself, large and sometimes tortuous, runs beneath the superficial varicose mass and often presents a second cystic dilatation just below the knee. The valves of the saphena are inadequate and there is sometimes a varix at the saphenous opening.

6. The saphena is very large throughout, its diameter being sometimes three-quarters of an inch. From the middle of the thigh to below the knee it is extremely tortuous, the bends of the tortuosities being often very abrupt. The valves are practically non-existent and a varix at the saphenous opening is common.

7. A single large cyst of the saphena situated immediately below the middle of the thigh or just above the knee, of a size varying from a cherry to that of a pigeon's egg. The saphena itself is moderately dilated throughout and may be slightly tortuous at the inner side of the knee. As a rule, however, the cyst is the only abnormality *visible* in the thigh, although in the leg the radicles of the saphena are varicose, sometimes to an extreme degree. The saphenal valves are entirely inadequate and when the cyst is situated low down it not uncommonly communicates with the femoral or popliteal trunk by means of an ascending or descending branch of large size.

8. Two large cysts of the saphena, one situated below the middle of the thigh, the other opposite the knee. The saphena is much dilated and between the cysts is tortuous, standing out prominently. The lower of the two cysts often communicates with the femoral or popliteal trunk. There is almost always a varix at the saphenous opening and the saphenal valves are virtually wanting. The veins of the leg are varicose generally to a considerable degree.

It will thus be seen that these eight variations embrace three distinct classes of venous abnormality—one in which the varix is local and limited, the saphena being for practical purposes natural; a second in which the saphena is largely if not solely affected, its valves being wanting or inefficient; and a third class, in some respects the most important, in which direct lateral communication exists between some portion of the abnormal veins and the nearest deep venous channel—i.e., the femoral or popliteal vein as the case may be.

I have already explained the reasons for the proneness to thrombosis which each of the varieties of abnormality mentioned undoubtedly shows. In the cases in which the saphena is normal and no other gross communication with the deep veins exists the varicose mass is so isolated that there are, if ordinary care be observed in treatment, no serious grounds for fearing that extension of clot to the great vessels will take place. In the cases, however, where the saphena is seriously involved, its valves being virtually non-existent, and in the cases associated with a direct lateral communication between the varix and the nearest deep trunk, the rapidity with which thrombus invades the deep channels is remarkable and sometimes appalling. I may perhaps venture to

Digitized by Google

say here, in parenthesis, that the extension of a thrombus in a vein is not checked only by the nearest collateral branch, as would be inferred from the teaching of the books, but also by the vein-valves provided that they are perfect—a fact which, although I believe it is not commonly recognised can be easily verified by any intelligent person who will watch the progress of a thrombus creeping along the length of a normal saphena vein. The rapidity with which a greatly enlarged valveless saphena will fill with clot from the knee to the groin is very extraordinary. The existence of a distinct sacculation of a vein, although primarily conducive to clotting, is up to a certain point antagonistic to the spreading of the clot, since this tends at first to confine itself to the sacculation, but the usual methods of treatment are not such as to take advantage of this help, and the thrombus therefore frequently extends into the vein and grows up its channel in the ordinary manner. A characteristic example of cyst thrombus, showing the disastrous results which may follow inadequate treatment, is afforded by the following case.

A woman, aged thirty years, a cook, unmarried, was sent to me at St. George's Hospital on account of varix of the lower limb. Upon examination there was found to be a large saphenal sacculation a little below the middle of the thigh, the saphena itself being very large throughout. I advised removal of the cyst and adjacent portions of the saphena in consequence of the risk of thrombosis entailed by her occupation. Her own disinclination and the advice of others led to the operation being declined. Three months later she was admitted with thrombosis entirely limited to the cyst, the saphena being quite soft and free from clot. Feeling certain that sooner or later the clot would invade the saphena and travel to the deep main vein I urged either the removal of the cyst with its contained clot or ligature of the healthy saphena above to prevent the upward progress of the thrombus. Again the operation was declined. Treatment by the usual methods was therefore carefully carried out. On the fourth day after admission the saphena became almost suddenly filled with clot from the cyst to the groin and blocking of the femoral and iliac veins followed immediately. She subsequently died from septic pneumonia the result of three successive embolic infarcts.

I presume there can be no reason for doubting that if I had been allowed to operate whilst the thrombus was confined to the cyst the life of this patient would have been saved. Although this may possibly be regarded as an extreme case it is not the only one of the kind which I have known to end fatally. Of similar cases in which permanent crippling of the limb has resulted from the invasion of the deep veins by thrombus in consequence of the importance of energetic treatment not being realised I could give many examples. Of the gravity of the lateral communication between the varix and the nearest deep venous channel I have had considerable clinical experience; the following is a good illustration.

A healthy young woman consulted me with reference to varicose veins behind the knee. She was an energetic horsewoman and she was induced to seek advice because at the end of a day's hunting the mass of veins became full and sensitive in consequence of the pressure of the pommel of the saddle. Upon examination there was well-marked varix of the kind indicated in Type 4; it occupied the inner side of the popliteal space and obviously dipped down as a large branch to end in the popliteal vein or the extreme end of the short saphena. I strongly urged removal of the varix, because I felt sure that unless riding was given up thrombus of the varix would occur some day, a crippled limb and possibly risk to life probably following in consequence of the invasion of the popliteal and femoral veins by the clot. Operation being at the time inconvenient to the patient it was postponed to a future date. About three months later thrombus of the varix occurred in the way I had anticipated, the femoral vein becoming very quickly involved; the saphena remained quite healthy and free from clot. The patient progressed in the ordinary way with rest, but the limb has never recovered its normal condition. It is larger than its fellow and becomes œdematous towards the latter end of the day; the saphena has become dilated and tortuous.

It is quite clear that the extension to the deep veins in this case took place through the immediate communication with those vessels and not through the saphena; it is, I think, equally certain that had the treatment I recommended been carried out the crippling of the limb would have been avoided. This particular type of varix may be regarded as especially important in horsewomen. I have no knowledge of any fatal case but I could quote other instances in which permanent crippling has occurred in the manner described. The crampy pains not uncommonly associated with varix of the legs, especially in persons of middle age, are, I believe, due to thrombus of the intramuscular veins. I called attention to this point in a lecture published in January last.[2] These crampy pains are acute and transient, but they often leave a sense of stiffness about the part, over which there is usually slight tenderness occasionally followed by local spots of discolouration; they are therefore easily distinguished from ordinary cramp. The occurrence of these pains is a sure indication of coming increase in the varicosity and has a definite bearing upon treatment.

THE SPONTANEOUS DISAPPEARANCE OF VARIX.

At present I have spoken of thrombosis in varix as a harmful factor only, which as a rule it undoubtedly is, the degree of mischief occasioned by it varying from temporary inconvenience to a fatal lesion. Sometimes, however, a thrombus exercises a beneficial influence which is deserving of recognition since it leads at times to what may in a sense be termed spontaneous cure. For the attainment of this desirable end organisation of the thrombus with complete occlusion of a considerable length of the affected vessel is essential. Few things are more remarkable than the changes which constantly take place in the varicose veins in the legs of old people in whom passive thrombus is of frequent occurrence and generally gives rise to so little discomfort when confined to unimportant vessels that it barely attracts notice. A careful examination of varicose veins in old people will often reveal the existence of innumerable obliterated venous areas with or without phleboliths which are the outcome of thrombosis. In a subject of any age the effect upon a varicose limb below the knee of a thrombus of the saphena which ends in organisation and occlusion of the vessel is remarkable, being in fact the same up to a certain point as that which follows the removal of a portion of the saphena by operation. Unfortunately in varix of the saphena organisation of thrombus is the rare exception, softening being the rule. The most complete example of spontaneous cure of varix by thrombus is seen in varicocele, in which occasionally a cure as perfect as can be effected by the most radical operation will follow thrombosis which is commonly traumatic in origin but may in gouty subjects be spontaneous. Extensive thrombosis in varicocele is more common than is generally supposed; sometimes the condition is, I fancy, not recognised when it does occur. I have myself seen a case in which a diagnosis of gouty orchitis had been made in consequence of some effusion in the tunica vaginalis which is prone to occur in thrombosis of the spermatic plexus of veins. The most striking case of spontaneous cure of varix following upon thrombosis with which I have met is the following.

A man, aged twenty-seven years, came to St. George's Hospital for advice concerning a varicocele which had begun to give discomfort after he had been lifting heavy weights. There was a large varicocele which I caused to be photographed, as it illustrated a point in which I was interested; it was arranged that the patient should be admitted into the hospital for operation at a later date. Three weeks after I saw him he returned, his varicocele having been struck by a heavy box which slipped as he was lifting it. The left side of the scrotum was bruised and a small, sausage-shaped, slightly tender and somewhat boggy swelling, extending from the groin to the testicle, occupied the place of the varicocele; the testicle was unaffected but there was a little fluid in the tunica vaginalis. He was prevented for reasons which were to him sufficient from coming into the hospital for treatment and I saw nothing more of the man until a year later, when he came for advice because he thought his left testicle was dwindling away. Upon examination the testicle was certainly smaller and softer than that on the opposite side, although at first sight it seemed of the same size as there was some slight effusion into the tunica vaginalis. The varicocele had entirely disappeared; just above the testicle was an elongated hard mass of the size and shape of a date-stone. There was neither pain, tenderness, nor discomfort of any kind. He stated that the swelling resulting from the

[2] Clinical Journal, Jan. 19th, 1898

Digitized by Google

injury had gradually disappeared after he had laid up for a fortnight and that since its disappearance he had suffered no inconvenience whatever although he had been doing his ordinary heavy work.

I have memoranda of 5 other cases (one in a medical man) of spontaneous cure of varicocele following upon thrombosis, in 3 the result of traumatism, and in the remaining 2 apparently spontaneous in gouty subjects. In the case described above there was certainly some testicular wasting in the true sense, and in one of the gouty cases the testicle atrophied to an extreme degree, nothing remaining beyond a small insensitive nodule. I have no knowledge of any mention elsewhere of the spontaneous cure of varix in this way. It is sometimes stated that varicocele disappears in old age, and I have been assured that this is the case by a surgeon of great experience who tells me he has never seen a varicocele in an old man. This is entirely opposed to my own experience, for I have seen varicoccles in old people not very rarely; an old gentleman, for example, of whom I had seen a great deal for many years, who recently died at a great age, had a very large varicocele for which he wore a support to the day of his death. At the same time it must be admitted that varicocele does at times undergo changes which tend to great diminution in size upon the decadence of testicular function, but I am strongly inclined to the belief that the changes which lead to complete disappearance of varicocele in old age are due to passive thrombosis of the spermatic veins, a view which receives some support from the frequency with which phleboliths and local occlusions are found in the veins of the spermatic cord in persons advanced in years.

THE TREATMENT OF VARIX.

The remarks I have to make upon the ordinary palliative treatment of varix are, I fear, rather elementary but they will not detain you long. In the early stage of the complaint, especially if there be a tendency to œdema, the results of massage properly applied are beneficial often to a remarkable degree; in its employment some discrimination is requisite. It is to be avoided in cases in which obvious cystic dilatations are present, and when any indications of recent thrombosis are manifest it is therefore, for example, inapplicable during the occurrence of the crampy pains to which I have referred. Moderate exercise in the absence of recent thrombosis is in all cases good; excessive exercise or overstrain is necessarily bad; worst of all is standing for a long time in the same position. In all cases rest in the recumbent position with the legs raised for an hour or so in the afternoon of each day is advantageous if practicable. Electricity in addition to massage is said by some to effect great results; personally I have seen no permanent good in excess of that obtainable by massage alone come of the combined method.

There is probably hardly anything which produces so much harm in varix as the routine use of elastic support, whether this takes the form of stockings or of bandages. I believe I am right in saying that 25 per cent. of the cases of varix in which real trouble arises are due to the use of elastic and other supports which are either unneccessary or ill-fitting. In individuals following ordinary occupations varix which causes no trouble and shows no tendency to increase should be left alone unless for reasons presently to be mentioned operation is indicated. At first sight it may appear that an elastic support, if it is not actually necessary, can at all events do no harm. Nothing, however, is farther from the fact than this assumption. That varix is often discovered quite accidentally is a matter of common knowledge and the discovery, unless ignored altogether by the subject, is generally followed by the wearing of an elastic support of some kind, often with the worst result possible.

It is not uncommon in my experience to find people who have been the subject of varicose veins in the lower limbs for years which have never given trouble of any kind begin to complain of discomfort and perhaps increase in the condition not long after having taken to the use of elastic stockings recommended casually by some friend. These stockings are frequently obtained after a rough-and-ready measurement from a druggist, coöperative stores, or wholesale house, where they are kept in "stock" sizes; hence they rarely if ever fit and the almost inevitable result of the wearing of an ill-fitting stocking in varix is an increase in the disease or the occurrence of some undesirable complication. It is essential if an elastic stocking be used that it should fit perfectly, and it is, so far as I can judge, one of the most difficult of appliances to obtain perfect. In varix confined to the leg the harm done by ill-fitting supports or badly-applied bandages is less than in varix affecting the thigh. I have seen 4 cases of grave thrombosis in the thigh undoubtedly caused directly by ill-fitting appliances. I therefore never allow a patient suffering from uncomplicated varix of the thigh to use any support above the knee, not only because serious complications are sometimes so caused, but because all the comfort obtainable in uncomplicated varix of the lower limb can be afforded by a properly arranged support which does not extend beyond the upper limit of the leg. In certain cases of œdema of the whole lower limb elastic support throughout may be indicated; in such circumstances the thigh piece of the support should invariably be made distinct from that of the leg, the two parts should never be continuous.

In passing I must here mention that there is a well-marked type of varix met with in a considerable percentage of the cases coming under observation in which the vessels are abnormal only inasmuch as they are large and somewhat tortuous, the valves being natural and the functional properties perfect. This is especially the condition found in the varix of the lower limbs which is often accidentally discovered either soon after puberty or at about the age of twenty or twenty-one years. In some of these cases the main artery of the limb is abnormally large. It is, in the absence of symptoms pointing to its desirability, as unreasonable in a case of this sort to use an artificial support as it would be to do so in a normal limb. Varix of the leg arising from deep thrombosis after injury in the manner already indicated requires gentle elastic support from the beginning with intelligent massage as soon as any tenderness has disappeared; by these means a cure in the true sense can often be effected, the use of the elastic support being generally necessary for about twelve months, after which it may be discontinued. The operative treatment of varix has now been freely practised sufficiently long to enable a proper estimate of its value to be made. It is a treatment with very distinct limitations in its scope and application, more discrimination being required in its successful employment than is, I venture to think, commonly supposed.

There are few treatments which, speaking generally, are liable to cause more disappointments to the patients than operations upon varicose veins, but with reasonable care these disappointments can be avoided, since when occurring they are inevitably due either to exaggeration on the part of the surgeon in the estimate of the benefits obtainable by the treatment, to want of judgment in the selection of cases, to the performance of unsuitable operations, or to the wrongful attribution of symptoms to varix which are in reality dependent upon some other condition. With regard to the first of these reasons it must at once be admitted that excepting certain cases of isolated cysts and local congenital masses of varix anything like a cure in the sense in which patients usually understand the term is impossible. In general varix the utmost which can be achieved by operation may be summed up in the relief of certain discomforts, a partial diminution in the objective defect or arrest of its progress if it be increasing, the prevention of subsequent inconvenient complications, and the removal in some instances of conditions which may prove dangerous to the integrity of the limb or possibly to life—prospects assuredly sufficient to justify the operative treatment when properly applied, but not of a kind to justify the use of the word "cure."

In discussing the question of operation with patients two points in particular cannot be too prominently borne in mind; the first being that if the disease has involved the saphena in the thigh the operation will not necessarily enable the use of an elastic support to be entirely dispensed with; the second is that in a case of long existing varix which has given rise to inconvenience an operation, although it will if the case is suitable effect improvement and give great relief, does not necessarily place the patient in the condition of a sound person. If these points be insisted upon much disappointment will be avoided, for there is no doubt that at the present time the tendency of the public is to expect very much more perfect results from surgical operations generally than can in the great majority of instances be effected by them. Operation in uncomplicated varix is to be regarded as a measure for the prevention of certain complications and as a check to the progress of the disease and not in any sense as a cure, excepting in the local conditions which I have indicated.

Digitized by Google

From the point of view of operation varix of the lower limbs may be divided roughly into two classes—one in which the defect is local with well-defined limits, the other in which the disease is more or less general, the long saphena being considerably implicated. There is no doubt whatever that local masses of varix, which are always congenital, occurring in persons of active habits should be removed, especially if situated in positions liable to injury or if there is any evidence of a direct communication with the deep main venous channels, in consequence of the danger connected with thrombosis under those circumstances; isolated cysts or dilatations, with the exception of those occurring in insignificant venous radicles, should be removed for the same reason. Cases in the second class, again, come under two denominations—one in which the disease is confined to the leg, the other in which it affects the thigh, the saphena being grossly involved. Speaking generally, if the disease is confined to the leg operation is useless; sometimes it is harmful. All the benefit obtainable from treatment of general varix of the leg can be obtained by properly applied elastic support which would still be necessary in the vast majority of cases if an operation were performed. In cases, however, which are not very unfrequently met with, in which in general varix there exists either a cystic dilatation of the long or short saphena about the middle of the leg operation in active subjects is certainly indicated. The condition, however, in this class of case which most urgently calls for removal is a very tortuous and dilated thin-walled vessel passing obliquely across the shin, which is especially dangerous in footballers and other persons liable to injury in the locality concerned. I have known this particular vessel to be the starting-point of serious thrombosis in three cases, and extensive subcutaneous hæmorrhage resulting from its laceration or rupture from traumatism is in my experience not very rare.

When the saphena in the thigh is involved, there being at the same time, as is practically always the case, extensive varix of the leg, the results of operation are most striking. The conditions mentioned as occurring in the "dangerous region" can be entirely removed, all risks to the integrity of the limb or to life being thus obviated. It is, moreover, perfectly clear from my experience that the discomforts felt in the leg in general varix and the tendency of the disease to increase depend almost entirely upon the pressure of the long column of blood in the valveless saphena. In practice it will be found that if this column be sufficiently interrupted the discomforts felt below are in all cases greatly modified and in the majority entirely removed, the tendency to increase in the varicosity is as a rule checked and in many cases very considerable shrinking of the varicose vessels above and below follows. In the selection of a plan of operation the point to which I have just alluded becomes of paramount importance, for although I know that there is room for difference of opinion in the matter I have proved in my own practice and have sufficiently corroborated the results of my own experience by what I have seen occurring in cases operated upon by others, that operative measures confined to the parts below the knee in general varix are useless. I have therefore long since abandoned them. My practice is to remove a length of the saphena extending from the point below the knee at which the two venous trunks from the leg join to a point a little above the lowest third of the thigh. In no case, so far as I can recollect, has there been reason to be disappointed with the result, although in many cases the amount of varix in the leg has been enormously in excess of that in the saphena above. On the other hand, I have seen instances in which thirty or more small pieces of vein have been removed from the leg in cases of this kind without any benefit whatever resulting until the saphena in the thigh has been dealt with. Indeed, in two cases which have come under my observation after having been operated upon in this way the subsequent state has been far worse than the condition before the treatment. The operation which I recommend occupies a comparatively short time in its performance, the wound is in a part which heals quickly, and the difficulty sometimes met with in keeping a large number of small wounds aseptic does not, of course, arise. I have a vivid recollection of a varicose limb in which not less than fifty short pieces of vein had been excised, the operation, it was stated, having occupied two hours; the limb when I saw it three months after the operation was œdematous, some of the scars were hypersensitive and irritable, whilst between some of them were thrombosed veins; the thrombi, it is true, were comparatively harmless as they were quite isolated, but they were distinctly antagonistic to rapid progress.

It is, I presume, needless to say that operation in varix the result of thrombosis so long as the dilated veins are concerned in carrying on the collateral circulation is unjustifiable—hence no operation should be performed in such cases if there is œdema or if the limb is manifestly increased in size generally. If, however, in cases of varix due to thrombosis there is no sign of œdema and the limb is not appreciably larger than that on the opposite side, they may be dealt with as ordinary cases of uncomplicated varix.

In those who are the subjects of extensive varicosity of the lower limb, whose occupation or amusements are such as to throw great or sudden strain upon the abnormal vessels, resection of a portion of the saphena in the manner which I have mentioned is strongly indicated if any feeling of tension in the vessels is perceptible to the person concerned during great exertion, although at other times no trouble or discomfort of any kind may be experienced. Failing operation in such cases, an elastic support extending only to the upper end of the leg should be worn during the continuance of the conditions leading to the liability to strain.

At first sight it would seem almost impossible to attribute to varix symptoms caused by some other condition, but in practice this is not altogether difficult. I have myself, somewhat against my will it is true, operated upon a case in which symptoms ascribed to varix were undoubtedly in no way connected with it. The case has already been recorded, but it affords such an excellent clinical illustration that I repeat its salient points. The patient was a man engaged in an active occupation, to whom, therefore, the ability to take a large amount of exercise was a necessity. He consulted me on account of general varix of both lower limbs and he described symptoms which might with reason have been thought due to the condition of the veins. His principal complaint was a feeling of fatigue and general fulness of the limbs at the latter part of the day; sometimes he suffered from cramp, and he described a puffiness about the ankles which was stated to occur after more than ordinary exercise. The symptoms are, I need hardly say, similar to those very commonly seen in varix. In this particular case, however, I could not satisfy myself that the abnormal veins were the cause of the trouble. I therefore advised him against operation. A few weeks later he returned having assured himself that the whole of his trouble was connected with the condition of the veins; he consequently asked me to operate. I stated that I was still averse to the operation and that I must not be blamed if no material good followed the treatment. The operation was subsequently performed with considerable benefit so far as the varix was concerned, but the symptoms complained of were not affected in any way so far as I could judge. A year later the patient was seen again. The symptoms had increased, and it was clear that they were due to an obscure nervous degeneration which was presumably incurable.

THE TREATMENT OF THROMBOSIS IN VARIX.

I have already indicated the local conditions which tend to the formation of thrombus in varix and have also shown how by the removal of certain abnormalities all risk of the complication may be avoided. I now come to the final and, in some respects, the most important matter to which I wish to call attention—viz., the treatment of thrombosis in varix. Having regard to what has been said of the tendency to thrombus in varicose and valveless veins to travel rapidly and invade the main deep veins, there can be no doubt that in the vast majority of cases the interest of the patient is best consulted by the removal at once, if practicable, of the thrombosed vessel with the whole of its contained clot, in cysts and in local masses of varix in which there is reason to suspect gross direct communication with the deep veins this treatment being peculiarly appropriate. Not only does the extirpation of the thrombosed vessel remove the liability of the deep veins to become involved and ensure a speedy recovery, the convalescence being represented by the time occupied by the healing of the operation wound instead of the tedious delay of weeks or even months involved in the orthodox treatment by rest, but it also prevents recurrence of the thrombosis, a matter of no small importance, seeing that in the majority of cases in which thrombus has once formed recurrence happens, sometimes frequently, each recurrence involving the same risks to the integrity of the limb or perhaps to life which were

Digitized by Google

associated with the original attack. Moreover, it is undeniable that in those cases in which recurrence occurs crippling of the limb, if nothing worse, finally ensues, for although it may be true that actual lameness need not follow, so much care has to be taken in the ordinary use of the limb to guard against further thrombosis that it can hardly in the true sense be considered sound. Complete removal of the thrombosed vein in some instances may not be desirable, the portion of the vessel concerned being, for example, so long that the operation requisite for its removal may be under certain circumstances considered too severe. The main object of the surgeon should then be to prevent the extension of the thrombus to the great deep veins of the part. In the lower limb this access to the deep vessels in varix is usually through the large valveless saphena. Writing ten years ago, I strongly advocated in creeping thrombus of the saphena the placing of a ligature around the vessel on the proximal side of the clot with a view to arresting its progress. At the time of making this suggestion no opportunity for carying it out had offered itself, but I have since practised the method (modified to the extent of dividing the vessel between two ligatures) in several cases, in none of which has the thrombus extended beyond the point of ligature, although in each case it rapidly reached the point of artificial occlusion. It is not, I think, unreasonable, seeing the rapid extension of the clot to the point of ligature, to conclude that the integrity of the limb, and possibly life, in these cases was saved by the energetic treatment which was carried out. After ligature thus applied the portion of the vessel thrombosed may be subsequently removed at a convenient time if necessary. If there is any evidence of the existence of a direct communication between the varix and the deep veins excision of the part affected and not ligature of the saphena is obviously indicated.

A certain number of cases of thrombosis in varix lead to embolism resulting in sudden death or in pulmonary lesions of more or less gravity. In the former case the surgeon, of course, is powerless, but in the latter condition, when there is a tendency, as is not unfrequently the case, to repeated detachments of emboli, I have sufficient proof to show that incalculable good can be done by surgical means provided that action is taken speedily and boldly. As the result of practical experience I have come to the belief that when embolism has followed upon thrombosis of any of the conditions referred to as existing in the "dangerous region of varix" it is the duty of the surgeon at once either to remove the source from which the emboli are derived or to interrupt by ligature if possible the channel by which they reach the central parts. It is at once clear that such treatment must, if it is to be successful, be in the majority of cases carried out before the thrombus has invaded the deep veins. With reference to this point it is interesting to note that if embolism does follow thrombosis in varix it almost always, so far as I have seen, occurs before the clot has invaded the deep vessels. The implication of the deep vessels, if it has already taken place at the time of the detachment of the embolus, does not negative the possibility of good from the radical treatment which I recommend if the original seat of the thrombus has more than one communication with the deep vessels. For example, a cyst of the saphena in the dangerous region which has become thrombosed may have a direct communication with the deep vessels which has given rise to their rapid implication, whilst the saphena itself may be free and be the channel by which thrombus or embolism may be conducted to the central parts. In such a case removal of the original seat of thrombosis is rationally indicated, especially if the thrombus is showing signs of softening, the period of softening of course being the time at which the tendency to embolism is the greatest. The following will serve as a good clinical illustration of the apparent benefit derivable from operations under the circumstances just indicated.

I was consulted by a tall, heavy subject, about forty-three years of age, with reference to varix of the left lower limb. The whole limb was affected; the long saphena was very large and just above the level of the knee it was involved in a cystic dilatation of about the size of a walnut. The main object of the consultation was to ascertain whether the condition of the veins was any bar to cycling, very little other exercise being taken. I strongly urged the removal of the cyst with the neighbouring part of the saphena, because although I could not of course say with certainty that trouble would arise from it I thought it very probable that such would be the case. My opinion was considerably influenced by the fact that the cyst was in the situation in which a direct communication between the varix and the deep veins sometimes exists. Although the patient himself was inclined to submit to operation the adverse counsels of others prevailed and I saw nothing further of him until about twelve months afterwards, when I received a summons from the country asking me to meet him at his house as he was in trouble. Upon seeing him I found the large saphenal cyst packed with clot, the result, he declared, of a slight strain which he distinctly felt whilst cycling. There were acute local pain and redness with a high temperature (102°). The patient was extremely sensitive and nervous and although I felt that immediate operation was indicated seeing the very large size of the saphena it was deferred for reasons at the time sufficient. A week later the thrombus passed a short distance up the saphena and then remained stationary for another week. At this time without any increase in the thrombus in the saphena a very severe attack of sudden cardiac pain followed by acute dyspnœa occurred; two other very slight attacks succeeded rapidly and three days later an attack of cardiac pain and dyspnœa which nearly proved fatal suddenly supervened. After each of these attacks the local signs of pulmonary lesion from embolic infarct were present. The patient was by this time desperately ill and it seemed quite clear that if another embolus became detached the case must terminate fatally. I therefore, with the concurrence of a distinguished physician, removed the thrombosed portion of the saphena and cyst. An immediate improvement followed the operation, no further embolism occurred, and a steady although slow convalescence succeeded in spite of some indication of thrombosis of the deep veins which was just beginning to show itself at the time of the operation. The parts after removal showed that the saphena was quite free from thrombus at a point about 2 in. above the cyst, being packed with firm, healthy clot up to that level. The cyst was full of clot, which towards its inner side was softening. This softened clot, which to the naked eye was indistinguishable from pus, extended down a branch of considerable size which, leaving the cyst wall, passed deeply into the limb, extending, so far as could be judged from its length and direction, in the upper part of the popliteal or the commencement of the femoral vein.

It can hardly be denied that this is a very striking case. I suppose there is little room for doubting that the emboli which nearly killed the patient were derived from the softened clot extending along the branch passing directly to the deep vessels. Taking all the circumstances of the case into consideration it is, I submit, perfectly reasonable to assume that the removal of the parts concerned saved the patient's life. I have had experience of other similar cases in which the detachment of emboli ceased after operations of the kind now described. It must not be understood that I wish to recommend operation in all cases of thrombosis in varix, since every case must of necessity be judged according to its merits, but speaking generally the principle is, in my opinion, sound and the treatment is one which should always be carefully considered in cases of the kind.

Such are the views upon some of the points of interest connected with varix which I venture to submit as worthy of attention. It would be, I fear, unreasonable to assume that they will meet with the approval of everyone; they are, however, based upon the careful study of a great number of cases of a common complaint in which a large experience is not very difficult to obtain. I can at least say with certainty, unless my experience is strangely at fault, that the treatment of varix, if conducted upon the lines which I have endeavoured to indicate, will prove entirely satisfactory alike to the patient and the practitioner.

WATER-SUPPLY OF PONTYPRIDD.—At a meeting of the Pontypridd Town Council held on Oct. 4th Mr. Howard Davies, M.R.C.S. Eng., L.S.A., medical officer of health, stated that although the water supplied to the town was free from evidence of animal or sewage contamination it was largely impregnated with vegetable impurity. The principal ill effects manifested from drinking the water had been due to gastro-intestinal irritation. Mr. Davies added that the Pontypridd Waterworks Company supplied 80,000 persons with water and he had frequently been obliged to complain of its quantity and quality. Other complaints were received from medical men in reference to the water. After a lengthy discussion the council resolved to refer the matter to the Sanitary Committee.

An Introductory Address
ON
MODERN UNIVERSITIES.

Delivered at the Opening of the Winter Session of the Medical School at University College, Cardiff, on Oct. 7th, 1898,

BY ROBERT SAUNDBY, M.D. EDIN., LL.D. (*hon. causâ*) MCGILL, F.R.C.P. LOND.,
PROFESSOR OF MEDICINE AT MASON UNIVERSITY COLLEGE; PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM; AND PRESIDENT OF THE COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.

GENTLEMEN,—I am honoured by being asked to address you at the opening of your winter session and to have this opportunity of seeing your College, of meeting your teaching staff, and of saying a few words of welcome to those who commence as well as to those who rejoin their classes in the medical school. Before going on I desire to say how much I regret the absence from ill-health of our friend Professor Haycraft, and I am sure you share my hope that he may speedily be restored to health and to those studies by which he has built up a brilliant reputation for himself and has conferred lustre upon this College.

I should like to congratulate you, as students of medicine, upon the career you have chosen. There may be professions in which the work is better paid and less exacting, but there is none the practice of which affords the same varied interest if we come to our work in the proper spirit, that of naturalists or observers of nature. The present is the time for you to cultivate this faculty, and for this purpose may I urge you to study botany, not in books only, but in the laboratory and the field on every opportunity. This practice will not only initiate you into scientific methods and familiarise you with the great principles of organic structure and function, but will form the groundwork of a study which in many of the phases of life opened up by a medical career may very reasonably be pursued with pleasure and profit. Therefore neither despise this study nor regard it as of merely passing interest. Make a point of going to every botanical excursion, for you will find that you can learn more from these pleasant holidays than from much reading of books.

I hope you will excuse me for having fallen into the temptation which such an opportunity as the present affords to offer advice. But as I have said so much, will you bear with me if I make another suggestion? Learn to read French and German with such facility that the periodical scientific literature of these two great nations shall be open to you. Nothing is easier than the acquisition of this amount of knowledge, as it requires only a dictionary, a reading book, and a sufficient stock of perseverance. Above all, recollect that you are not here merely to learn how to pass certain examinations, although that is a duty which has to be kept in mind. Most of you will have in these few years of study your only opportunity of obtaining systematic instruction in scientific principles. You may not learn here how to diagnose measles or to treat whooping-cough, but you ought to acquire what is of far more importance, those habits of scientific thought which will make you accurate diagnosticians and rational practitioners.

You are fortunate in the conditions under which you are beginning your professional studies. You are students in a College possessing faculties of Arts and Science, in which students may proceed to the degree of B.A., B.Sc., &c., so that you are associated at the outset of your professional education with a broader culture than that of a purely medical school. I hope many of you have taken advantage of that wider instruction before beginning your present studies. You are alumni of a College which is a constituent part of a university. The University of Wales is the youngest institution of its kind in the kingdom, and, like all young things, it is interesting because of the immense possibilities for good or evil which lurk behind the veil that hides its future. My interest is of the most sympathetic kind, for no one recognises more than I do the influences for good which such a university may exercise under proper conditions. Doubtless for sufficient reasons your College does not attempt to give a complete course of medical instruction, but it limits its functions to the first two years of professional study—that is to say, you are taught here only botany, geology, chemistry, physics, anatomy, physiology, materia medica, and pharmacy. I should like to suggest the addition of bacteriology to this list as being most fittingly taught in its broad general principles during these preliminary years. Although there can be no difficulty in completing your school by the addition of chairs of medicine, surgery, &c., whenever your council shall see fit, there is such a well-marked natural line dividing the subjects taught from those omitted that students may without disadvantage study here for two years and then proceed to some other great school for the concluding part of the curriculum. The Principality of Wales may be proud of these first steps in the development of its medical school and should rejoice that that school is connected with its university.

English medical education has unfortunately proceeded upon other lines. The English medical schools have been purely professional training places and have grown up in connexion with our great hospitals. They have given an excellent practical training, but their deficiencies in other respects have of late years become too obvious to be denied. Hence has arisen the demand for a university for London which shall be really a place of teaching and with which the medical schools of London may become properly related. In Scotland the national universities having their seats in populous centres and not despising the encouragement of "bread-studies" have fostered flourishing medical schools which have derived great advantages from their university connexion and have contributed no little in return to the prosperity of those seats of learning. At St. Andrews alone has medical education stagnated, no doubt on account of the small size of the town; but the munificence of a nobleman well known in Cardiff, the Marquis of Bute, has now provided a building well equipped for the provision of just the same limited medical course as you have here, and it is to be hoped and anticipated, in view of the crowded state of the other Scottish medical schools, that a career of usefulness now lies before the St. Andrews Medical School.

Why is it that England should have shown herself in the past so strangely indifferent to university education; nay, one might say, so indifferent to education of all kinds? One hardly likes to say with the Bishop of London that the English public cares nothing for education, because it is difficult to conceive any apology for such an attitude which would not be too uncomplimentary to my fellow-countrymen. I am inclined to think better of them than this and to believe that it is mainly because of the sort of thing which has been so long associated in their minds with the word "education" that they care so little for it. What wonder is it if John Bull undervalues education when he sees how little learning results from four years at a great public school followed by three years at a greater university, each claiming to give the best education in the country? The day has hardly yet passed in which education at a great public school consisted in practising the art of writing bad Latin verses and the after years spent at a university still implied for the great majority no substantial addition to the scanty store of school-acquired learning. With universities and public schools in which play takes the place of work and the art of teaching is held of no account, why reproach the British public with want of care for education? The fault lies with our educationists, who neglect to teach, who despise the duty of preparing for the professions, and who have allowed the pursuit of athletics to be elevated to such a height that the future captains of the schools will not be the heads of the sixth forms but the captains of cricket, football, or boating clubs. Such an exaggerated estimate of athletics as at present finds favour in English public schools and universities is madness. It amounts to a vast waste of enormous national resources and is little short of a breach of trust on the part of heads of schools and colleges who cannot conscientiously believe that they are doing their duty to the boys confided to their care. We who, as teachers and examiners, have to do with the unfortunate products of the present public school system, know the extraordinary difficulty which they find in passing their examinations and we attribute this to their having undergone no previous mental discipline. They come to us without having acquired the power of application which it is above all the business of a schoolmaster to develop. No doubt there are hard-working grammar schools in our great cities, such as St. Paul's School in London and King Edward's

Digitized by Google

School in Birmingham, where teaching is still regarded as the duty of the teacher and application is required from the taught, but such schools have no corresponding universities to which to send their boys. They must go either to Oxford or to Cambridge, where the demon of athletics reigns supreme and where professional studies are deprecated if not despised. These universities, moreover, by reason of their remoteness from the paternal home and the consequent increased expense involved, are in many cases beyond the reach of those who desire and would profit by the educational opportunities which a university affords. In spite of public indifference and class prejudice the demand for more universities has made itself heard so far at least that charters have been granted to the Victoria University and to the University of Wales. In your own case there has been a recognition, if parsimonious, of the principle that the State must provide the necessary funds. We in Birmingham believe that a university is a necessary complement to the educational system of our city, and we are endeavouring with some success to take the needful steps for its establishment. But the great difficulty is the want of money. No one wishes a shabby, half-starved university, with a poor library, badly equipped laboratories, and an underpaid teaching staff. The ideal modern university must of necessity be an expensive institution. A few class-rooms grouped round a common hall can no longer suffice for its installation. Let me describe to you one of the smaller German universities—that of Strasburg—which has an annual attendance of about 1100 students and may therefore fairly serve as a model of a provincial university such as we should like to see, not only in Birmingham, but in other great English cities. The university buildings comprise forty special institutes fully equipped for teaching theology, law, philosophy, philology, geography, archæology, ancient and modern languages, chemistry, physiology, pathology, geology, physics, botany, pharmacy, pharmacology, bacteriology, &c. The maintenance of these buildings costs the University about 360,000 marks, or £18,000 sterling, per annum. The library contains 730,000 volumes and possesses an annual budget of 127,000 marks, or over £6000 sterling. The teaching staff consists of 56 ordinary professors, who divide among them 523,000 marks, or an average income of £465 per annum. There are 30 extraordinary (honorary) professors, 33 *privat-docenten*, and 2 lecturers, the last two classes of teachers being paid by students' fees. The total annual expenditure of the university amounts to 1,052,370 marks, or in round figures £52,000 sterling, of which sum the State contributes more than nine-tenths. No one who knows the Germans will say that they are an extravagant people and it is certain that money in many respects goes further among them than with us, so that we may assume that £50,000 a year is not an excessive estimate for the expenditure of a properly equipped modern university.

Where is the money to come from? There can only be one answer to this question—from the State. The State which has given free elementary education must complete its work and give not free but State-organised and State-equipped secondary and university education. The Lord President of the Council is reported to have said in a speech delivered by him not long ago in Manchester that it was impossible, and in his opinion undesirable, that universities should derive their main financial support from the State, for the reason that State assistance to such an extent would involve State control, and this he thought incompatible with the perfect and complete efficiency of an independent college. He admitted the indignity of colleges having to canvass for subscriptions and he saw no other source upon which they could rely than the generosity of private donors. It is not encouraging to have such opinions expressed by the official head of the educational business of the country. One can hardly believe that the speaker has got beyond the common English idea of a university as a luxury for the well-to-do. If the establishment of universities is for the benefit of the nation at large the nation must and will pay for them. Are they or are they not beneficial? This is the only question worthy of discussion. The objection that State control is opposed to university efficiency is contradicted by the experience of all civilised countries, England alone excepted, where, be it observed, it has never been tried. In Scotland the universities receive very substantial assistance from the State and this has not been accompanied by any paralysing effect. On the whole there is much to be said for a certain amount of State control, as in all university matters a Minister is a fairly impartial referee, able and willing to hear all sides of a question and to decide without respect to local considerations, and in the long run it is certain that national rights will never be sacrificed to those of a class, as has happened so often when funds have been placed in the keeping of private trustees. The worst of all evils in a university is the want of adequate funds, and I would rather see the establishment of our Birmingham University postponed for a generation than get one to-morrow which would be badly equipped and cramped in every direction, or, worse still, that it should under pressure of competition attempt too much and do nothing well. I trust we shall show a strong determination to work within modest limits until the public comes to our aid and insists upon proper State support being given to institutions able to put forward such claims upon the national purse.

What are these claims? The national importance of the work done and the impossibility of raising sufficient money in any other way. There are only three possible bases upon which a university can be carried on. The first of these is a commercial basis. University experience has failed to produce a satisfactory example of this type of institution, nor need we go to America for illustrations of the bad results which the commercial spirit, stimulated by want of funds, can produce in university affairs. The second basis is private benefaction or endowment, by which means great universities have been founded in America, but there is not the same rapid growth of wealth in this country, nor is there any modern instance here of the gift of such a vast sum as would be needed to build and endow a single university. No doubt there have been several cases in America, notably the Universities of Cornell and Johns Hopkins. To build and endow a modern university would require about two millions sterling, but even if this vast sum could be obtained it would not be under proper public control and there would be no guarantee that it would always be applied for the national benefit. Permanent endowments in private trusts are not the most desirable social institutions, and no country has more illustrations of money misapplied in this way than has England. To tell us, as did the Lord President of the Council at Manchester, that we must wait until some benevolent persons provide these vast sums is equivalent to postponing the foundation of suitable modern universities to the Greek Kalends. The third and only practicable basis for a university is that of State support, which has in its favour the very strong argument that it has been accepted by every civilised country in the world, England alone excepted. France spends 7,500,000 francs (£300,000) on university education, having nearly doubled the State contribution during recent years, for in 1870 it amounted to only 4,215,521 francs (£168,620). She has, moreover, found it desirable to encourage provincial towns to find funds for university buildings and has granted to each provincial faculty the title of "university," so that there are now 15 universities in France expending over 12,000,000 francs (£480,000), of which 7,500,000 francs, as already stated, are derived from the national exchequer. These 15 universities educate 26,000 students, which is in the proportion of one student to 1400 of the population of France, the cost of each student to the State being about £11 10*s*. Taking the population of France at 38,000,000 she has one university to about 2,500,000 of people. In the whole of Germany there are 21 universities, educating 30,000 students, giving a proportion of 2,100,000 persons to a university and one university student to 1400 of the general population. I cannot give you the total expenditure, but the Government contributions amount to upwards of 14,000,000 marks (£700,000) and the annual cost to the State of a university student is something like £23. England possesses 4 universities, not one of which is equipped so as to fulfil modern requirements. They are in the proportion of 1 to 6,500,000 of the population and they educate 9000 students, which number gives one university student to every 3000 persons. I am quoting these figures in order to show you what vast sums two great nations are now spending upon university education and to contrast with them the miserable £25,000 which our Government deems sufficient for the needs of England with a population of 27,000,000, whose welfare, livelihood, nay, very existence, depends upon the maintenance of the commercial and the industrial supremacy which the country has enjoyed for more than a hundred years, but which is in danger of ebbing away to better educated rivals. I may be told that the sort of education the university affords is not of much use in trade. This is the often heard fallacy, but even were

Digitized by Google

it true it is also true that education proceeds from above downwards and not from below upwards, and that if you want to improve our national education and to give it that practical character which is needed you must have teachers who are imbued with the modern spirit and have been educated in universities of the modern type. We hear a great deal of nonsense talked about the danger to a university if studies are pursued there for any other purpose than the love of learning, but we do not hear of the danger of stagnation which results when the university excludes from its walls all interest in the busy active life of the world. Does Oxford, where this doctrine is carefully cherished, contrast favourably with the universities of Germany, where professional training is not despised? Which is more in touch with modern thought? which contributes most to the progress of science or even of scholarship? The answer cannot be doubtful. I admit that in a country like ours, which is saturated with the commercial spirit, there cannot be so great a devotion to pure science and scholarship as in Germany, and it may be conceded that students, professors, and governing bodies in this country are all alike too apt to consider what will pay them best; but although this tendency needs a check it does not lead to the stagnation which takes place when an institution is shut off completely from the main stream of human interests and ambitions. In the modern university, just as the students go there not to play but to learn, the professors should be appointed to teach and to inspire a love of learning, not to enjoy leisured ease or the empty dignity of an academic title and position. Heaven forbid that I should suggest that the sole duty of a professor is the oral delivery of lectures in a class-room. I admit with regret the existing tendency in some quarters to impose far too much class-room teaching upon the professors, but there is the opposite extreme where the titular professor gives no lectures, takes no part in training anybody, or only delivers an occasional brief course which forms no part of the work of the student for his degree. The professor must not only teach but must be capable of inspiring a love of learning, to do which he must be himself a student, working at the head of his class, leading the way to new ideas, fresh facts, and broader inductions. The teaching of the professor must be supplemented by tutorial classes—*conférences* on the French and German plan, where all the talking is not on one side, where questions and answers bring out and test the student's knowledge, clear his ideas and fix them in his mind. Finally, there must be compulsory attendance at frequent written class examinations. Such work in the class-room should be in part the preparation for, in part the complement of, the work in the museums and laboratories. The modern student must not only read about the thing taught, but he must see it, and, if possible, handle it. This condition demands space and materials which cost money, but such a real and truth-promoting method will surely have the approval of a practical people and will not be allowed to lack the necessary means. I believe that the more the nation hears about modern educational methods the sooner the prejudice against university education will die away and the demand for the establishment of the necessary institutions will become irresistible. Unfortunately, it is not possible to demonstrate to a popular audience the work done in a laboratory. For popular instruction the lecture system is alone fitted, and popular lectures, that is, lectures which seek to be intelligible to persons who possess no previous training on the subject, must give a poor idea of the practical side of modern scientific education.

The passage through Parliament of the University of London Reconstruction Bill has given a final blow to the hapless idea that a university might be merely an examining board, whose students could be left to acquire instruction how and where they pleased. But a not less objectionable makeshift is now popular—namely, that of uniting together a number of different colleges, heterogeneous in essential features, situated perhaps in widely separated cities, composed of persons who cannot be expected or desired to see everything eye to eye with each other, possessing different aims and aspirations. From this ill-assorted union is formed a so-called federal university. The chief merit of the plan is that it economises parchment, but this hardly seems a sufficiently important ground for such a departure from the lines upon which universities have hitherto been successfully established. The failure of this method in Ireland is most conspicuous, and it is much to be regretted that it still finds favour with our educational rulers. It is of course for the State to determine in which centres universities shall be established, but it is impossible for a university to distribute itself satisfactorily over several different and distant places. The unfortunate result is a plurality of second-rate colleges and nowhere that superiority of at least some one department which gives character to a university and raises the tone of the whole of its teaching. I am aware that your university has been patched together in this way, but you are still in the early days of the experiment. I recognise that there may have been a difficulty in adopting any other plan, but it will be most unfortunate if the precedents of Victoria and of Wales are regarded by the Government as a justification for the extension of the process to other localities where no such reason exists. In reading the charter of your university I was much surprised at the prohibition against the possession of real property to a greater value than £10,000 per annum. At the present time the restriction is probably not very burdensome, but it is difficult to understand why a royal charter should impose a disability from which other corporate bodies are free, or why it is that the State which takes such a narrow view of its financial obligations towards university education should seek to hamper such institutions in the nature of the bequests they may receive or the investments they may hold. This restriction is in the spirit of the Mortmain Act, which, whatever its utility in the Middle Ages, is now out of date. The other disability imposed by your charter is the clause withholding the power to grant degrees in medicine. I suppose the reason for this was the non-existence of a medical school in connexion with either of your colleges, but I think it would have been better if the power had been granted subject to the supervision of the General Medical Council, which has statutory control over all qualifying examinations and courses of study. The relation of universities to medical education can be solved in only one of two ways: either the State as represented by the General Medical Council or some other statutory body must itself conduct qualifying examinations, or this work must be left to the universities and the State content itself with the right of supervision. On the whole the latter seems to be the plan which has the advantage, for it is not only that which at present exists, but it is the one which most civilised nations have adopted. I suspect that there was no great anxiety on the part of those who had to do with procuring this charter for what they perhaps considered the doubtful privilege of engaging in medical education. Unfortunately we know that such an objection exists in certain quarters and has played no small or doubtful part in hindering the progress of medical education in England. If Cambridge has within the last generation burst asunder the bonds of prejudice and has founded a flourishing medical school, Oxford still misapplies its medical endowments and declines to reorganise its medical faculty. I hope the University of Wales will always welcome medical students and I hope that when circumstances permit the completion of this medical school steps will be taken to acquire the necessary powers for conferring degrees in medicine.

The modern university, if it is to have popular support and to play the part that it should do in our national life, must not despise what the Germans call "bread-studies," but must feel pride in training men to be useful as well as learned citizens. Law, medicine, engineering, architecture and music are not unworthy to be associated with the most distinguished culture, and while those who study them in a university gain incalculable educational advantages, the university which undertakes these functions can be no loser from being thus brought into relation with the highest and best of the secular professions. I do not wish to disparage Oxford or Cambridge, which are delightful places for study and for amusement, affording a choice of either to those so fortunate as to be able to live there, but they are not and cannot be popular universities such as the nation needs. These must be seated in our great and populous cities and be near the homes of the youth of both sexes who demand university education. In such universities the study of ancient languages and higher mathematics cannot be allowed so preponderating a position as has been assigned to them at Oxford and Cambridge, although their educational value must be duly recognised. In this respect the University of Wales has begun well, the syllabus of its course of arts studies offering much worthy of imitation by similar bodies. There should be universities in Manchester, in Liverpool, in Birmingham, in Leeds, in Newcastle,

Digitized by Google

and in Bristol, and we should look forward to seeing one before long in Nottingham and another in Norwich or in some city of East Anglia. As already contended the new universities must be mainly supported by the State, but the Government may fairly claim that a certain proportion of both capital, expenditure, and income should be provided locally. This would afford some evidence of the reality of the demand. In the expenditure upon sites and buildings the Government might ask that half the cost should be borne by the localities, but a smaller proportion of the annual budget, such as a third or two-fifths, would be enough to stimulate local liberality and to prove the seriousness of the promoters. Once these institutions are established and get into working order I do not fear for their future. The good they will do will secure public recognition and will make it impossible for any Government to refuse whatever sums may be necessary to maintain their efficiency. This question of modern universities for our great cities is one in which all classes may be asked to interest themselves, for all are members of the commonwealth and share in the well-being. But it is a matter which especially concerns those who live by their own labour, whether of head or hands. This class is much larger than any other and under our democratic constitution is able to control the Government. The one thing necessary is to rouse it to a sense of its needs, and this work of awakening can be effectively carried on by every man who believes what I have said to be true. Our task is to explain the aim and the method of a modern university, to show the people the advantage to them of having near their reach such institutions in which their sons and their daughters may gain the advantages of a splendid practical education, and to urge that, following the example of other civilised Governments, it is the duty of our Government to aid by substantial money grants the formation without further delay of such universities in our principal English cities. I think the establishment of the succession duties affords an additional claim for Government help, as this heavy tax is levied upon those very sources of charitable bequest which the Lord President regards as the only available means for providing more universities. This tax has been so successful and the total amount of revenue now raised is so enormous that it is incredible we should go on spending so much upon the navy which is to protect our trade and so little upon the education which is needed to keep any trade to be protected.

Just one parting word to you to whom I am especially speaking to-night, the medical students of Cardiff. You have made choice of a noble profession. See to it that you live nobly, for if you wish to understand goodness or beauty or religion you must, as Schopenhauer says, evolve them in your lives. Time will bring its roses to all of you, but not to all fame or wealth. But if I cannot promise that you will all become medical baronets, or even medical knights, I can assure you that there is no profession in which success most certainly attends attention to business or in which so good an income can be as readily secured. Do not despise the expression "attention to business," for it is just in business qualities so many of us fail, and whatever the sphere in which your talents place you, the common virtues of industry, order, and punctuality will more than anything else determine the relative amount of your success. Bear in mind that success has its dangers and that the "millstone of poverty" (to quote Carlyle) may often be "the necessary ballast that keeps our centre of gravity right." No profession is more exposed to the temptation to petty acts of injustice or more in need of the prayer against envy, hatred, malice, and all uncharitableness. We are given to magnify trifles and quarrel over twopenny-halfpenny matters, talking much about ethics and doing things which are truly feminine in their petty meanness. We are prone to cry out against all that exists and to say with Jack Cade, "There shall be in England seven halfpenny loaves sold for a penny, the three-hooped pot shall have ten hoops, and I will make it felony to drink small beer." This revolutionary spirit, be it well understood, applies only to matters medical, for in general politics we are usually very conservative. The clamour for better pay and greater privileges depends in part upon inability to recognise the true position which we hold in society. That position depends mainly upon the public belief that we are a disinterested profession and that belief rests upon the vast amount of public work we do for nothing. But if we follow the advice of some of our friends and seek to put the market price upon all our services must we not reckon upon a change upon the part of the public which may not be to our advantage? Many acts which are full of grace and are accepted gratefully as free gifts become of doubtful value when the value has to be appraised in hard cash. Would not our relations with the public lose their character of friendly intimacy which now distinguishes them and in return for a more strict debit and credit account should we not find ourselves placed upon a purely business footing? Is it, therefore, certain that we should improve our position by seeking the uttermost farthing of the debt due to us? In your relations with your colleagues avoid giving offence and if you have any difference strive to make as little noise about the matter as possible. Do not indulge in personal controversies and shun the men who do.

"Surely after all
The noblest answer unto such
Is perfect silence when they brawl."

Be honest men and gentlemen. In time to come you will know the joy of wife and child, and with that substantial basis for your happiness you will find pleasure in your work and sufficient human and scientific interest to satisfy you so long as your lives shall last.

A CASE OF HYSTERICAL CONTRACTION OF THE FOREARM SUCCESSFULLY TREATED BY SUGGESTION.

BY SARAT K. MULLICK, M.B., C.M. EDIN.,
ASSISTANT PHYSICIAN AND REGISTRAR TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS, SOHO-SQUARE.

A GIRL, aged nine years, attended the out-patient department of the National Hospital for Diseases of the Heart and Paralysis on Oct. 21st, 1896, and was found to be suffering from mitral regurgitation with considerable enlargement of the heart. As she complained of faintness, dyspnœa, and palpitation on exertion it was obvious that there was a certain amount of failure of compensation, although the physical examination showed that the right side of the heart was still sound. The left arm was rigidly flexed at the second phalangeal joint with the hand extended on the forearm, and she was unable to open her hand or straighten her arm. The toes of her left foot were also crooked, and there was evidently loss of power in the flexor muscles, as the foot dropped to a certain extent in walking. The muscular affection appeared to date from eighteen months previously when she was said to have fallen down and to have been unconscious for some hours. On recovery her arm and leg were found to have lost power and she complained of pain in the back of her head. Seven months afterwards she had a similar attack and was unconscious for four or five days. The muscular condition was considered as probably due to hemiplegia of embolic origin and she was treated for the cardiac trouble as an out-patient. On Dec. 2nd, 1896, she was admitted into the hospital. After about two months' treatment she was discharged, her condition being greatly improved, but the fingers and toes being in much the same condition as when she was admitted. She continued to attend as an out-patient and was treated with citrate of iron and quinine. In March, 1897, she was put under electrical treatment and was faradaised regularly twice a week for about eleven months with no obvious benefit. In February, 1898, she was again admitted as an in-patient. The fingers and toes were, if anything, more contracted, the former being in the position shown in Fig. 1. In a few days I observed certain signs which led me to believe that there possibly might be an hysterical element in the case. I observed one night when she was soundly asleep that her fingers and toes were not flexed and that without disturbing her I could move them with the greatest ease. I further observed that when she walked about as she thought unobserved or when her attention was directed away from herself she could walk much more naturally and with greater facility than at other times. This instantly changed whenever she was watched. Moreover, on making a careful examination the muscles both of the arm and of the leg were found to be in no way abnormal as regards their electrical reaction nor was there any wasting. Taking these facts into consideration in conjunction with the history of recurrence I came to the conclusion that the spasmodic

Digitized by Google

contraction was not, as was originally supposed, a post-hemiplegic rigidity due to embolism resulting from the cardiac lesions but to hysteria. On arriving at this conclusion I determined to attempt to influence her by suggestion and made the first experiment on Feb. 15th.

Before being operated upon the patient was asked to open her fingers voluntarily, which she was unable to do. Then one by one her fingers were quickly forced open, but they at once went back to their original positions. Then the suggestion was tried in the presence of a nurse. Screens were put round the patient who was asked by me to look steadily into my eyes for a few minutes. Thereafter I opened out the fingers one by one, first the little finger, which offered the greatest resistance, then the others in their turn

FIG. 1.

which became increasingly easy to open. It was then suggested to her that she could keep them open, which she did for five minutes, after which they remained half flexed. Again they were put straight and remained so under my suggestion. The conviction was then brought home to the patient that if she liked she could always keep them open. In order to make this conviction lasting her affected hand with fingers extended was put upon a padded splint for nine hours. When taken off the fingers were quite straight. At first simple and then complicated manipulative exercises were tried. Gradually the stiffened fingers became pliable and in a week she was able to perform the most complicated movements. The toes were treated in the same way, with the exception that the padded splint was not used. When they

FIG. 2.

were half straight she was put on tip-toe exercises for ten minutes at a time. In the beginning of these exercises she was allowed to place her left hand on the table, flexing and extending her fingers with the double object of supporting the body and strengthening the fingers. As the toes became stronger the hand support was taken away. When in bed she was made to flex and extend her toes and fingers voluntarily for twenty and thirty minutes off and on daily. She left the hospital in a couple of months with her general condition greatly improved and her fingers and toes strong, pliable, and useful (see Fig. 2).

This case possesses considerable interest inasmuch as it is a typical example of a certain form of hysteria occurring at an unusually early age, and it is, moreover, an object-lesson in the danger of overlooking the true cause of a morbid condition in the presence of another adequate antecedent. The motor symptoms of hysteria are tremor, incoördination, spasm, and paresis, and in practice we commonly find the last two in combination as in the above case. The special points of interest in the case may be summarised as follows: 1. The age of the patient. It is only of recent years that we have recognised the fact that it is comparatively common to get well-marked hysteria in children. According to the statistics of Clopatt (quoted by Gilles de la Tourette), out of a total of 272 cases of hysteria occurring in children under fifteen years of age only 15 were in girls nine years of age. 2. The onset. Hysterical paralysis may commence suddenly or come on gradually. In this case it was ushered in by what was in all probability an hysterical fit, which was followed by a brief period of unconsciousness. 3. The recurrence. The patient recovered from the first attack and had a similar one seven months later the effects of which were more enduring. Such a recurrence is rare, but when it does occur it is absolutely diagnostic of hysteria. Richer in his work, "Paralysie et Contractures Hystériques," under the heading of "Paralysie Erratique," records such a case and others may be found scattered through the journals, but they are not frequent. 4. The electrical reaction of the muscles. In Richer's case there was abolition of the electrical contractility of certain groups of muscles. In the present case the electrical reactions were absolutely normal. 5. The parts affected. In hysterical spasm affecting the arm and leg it is usually the latter which is most affected. In this patient the contrary was the case. 6. Sensibility. Hyperæsthesia and anæsthesia so common in hysteria were not present in this patient. 7. The special senses were normal. 8. The type of the contraction. In most of the recorded cases of hysterical contraction of the forearm the hand has been flexed. In this case, on the contrary, the extensor muscles were chiefly involved and the hand was carried right back into a position at right angles with the forearm. 9. Tremor was entirely absent. 10. Treatment. After the failure of galvanism the patient was cured by simple suggestion. There was no attempt made to induce the state of trance, nor do I think it necessary. I have always found that cases which could be influenced for good by hypnotism could also equally benefit from simple suggestions if repeated often enough.

Soho-square, W.C.

PERFORATIVE APPENDICITIS; DIFFUSED PERITONITIS; DOUBLE LAPAROTOMY.[1]

BY ARTHUR MAUDE, L.R.C.P. LOND., M.R.C.S. ENG.,
AND
J. RONALDSON RUSSELL, M.R.C.S. ENG., L.R.C.P. LOND.

THE mortality from diffuse peritonitis secondary to perforative appendicitis is still so high that any individual cases saved by laparotomy are of value for statistical purposes. Of the 36 cases collected by Dr. H. P. Hawkins no less than 27 died, and according to Treves[2] of these cases (Hawkins's) those which died within a week of the onset of symptoms presented general peritonitis probably from the beginning. Out of 340 cases of appendicitis at the Methodist Episcopal Hospital[3] in ten years 11 had diffuse peritonitis, were operated on at an average of five days' duration, and 9 died. The dangers arising from early operation in the hands of even operators of very moderate experience, such as ourselves, are infinitesimal compared with the danger of diffused peritonitis. The good effected by merely draining the abdominal cavity was in this instance most striking.

A delicate boy, aged sixteen years, had presented no previous signs of abdominal trouble. On April 23rd, 1898, he began to ail, complaining of general colicky pain in the abdomen; micturition was frequent and painful. On the 25th he was worse and constant vomiting began. No action

[1] From notes by Mr. Maude.

Digitized by Google

of the bowels occurred after the 23rd. He was seen by Mr. Russell, who considered that he had probably a volvulus or some form of acute obstruction, though he was suspicious of general peritonitis from the first. He asked me to see him on the night of the 28th, when I found the abdomen distended, tympanitic, and intensely painful and tender. There was constant vomiting, not fæcal, no signs of intussusception, and no special signs pointing to typhlitis. We considered diffuse peritonitis certain and probably secondary to a volvulus or some appendix trouble. We tried large enemata gently administered and arranged for a laparotomy next day. His condition was then very threatening—vomiting was constant, the pulse was rapid and failing, and his general state was very bad. I decided to open in the middle line in the absence of any defined typhlitic symptoms and in order to be able to explore the peritoneum thoroughly. The peritoneal cavity was distended with intensely fœtid sero-pus. There were no adhesions in the upper part, but the right iliac fossa was almost shut off by loose recent adhesions. Finding no band or apparent intussusception and the boy's condition being very bad we decided not to explore the cæcum further but passed a drain down to it, flushed out the peritoneum with hot water, and closed the wound with fishing-gut sutures for the peritoneum and silk twist for the abdominal parietes. He rallied in a few hours and by next day the bowels acted naturally, his pulse fell to 80, and the vomiting ceased. The discharge from the general peritoneal cavity rapidly decreased, but intensely fœtid, necrotic-smelling pus coming still from the cæcal region, on May 18th I made an incision of 3½ in. parallel to Poupart's ligament, having its middle over McBurney's spot, and cut down into a double abscess cavity, at the bottom of which I found the appendix firmly bound down, curled up, shrivelled, and lying in contact with it a stercolith exactly resembling a cherry-stone. The median drain was removed and a fresh one inserted into the second wound. The median wound healed rapidly. The patient made a tedious but uneventful recovery, but the cæcal abscess cavity was slow in filling and a residual sinus remained for many months. In July he threatened a relapse of perityphlitic suppuration, the sinus being still open. As his circumstances were very poor we removed him to St. Bartholomew's Hospital, where Mr. Marsh kindly admitted him. Mr. Marsh opened up the sinus, and finding it superficial decided very judiciously not to explore further but to pack the sinus, which accordingly healed slowly by Sept. 2nd. The patient is now fat and well.

Remarks by Mr. MAUDE.—These operations were performed in a poor cottage in the country, where we had to bring even the sterilised water necessary. The patient had no professional nursing the whole time, though a trained and highly skilled nurse was in charge at each operation. The case reflects great credit on Mr. Russell, who conducted the dressings and assumed charge during this long period from April 30th to July 17th.

Westerham.

A CONTRIBUTION TO THE PATHOLOGY OF BERI-BERI.

BY W. GILMORE ELLIS, M.D. BRUX., M.R.C.S. ENG.,
MEDICAL SUPERINTENDENT, GOVERNMENT LUNATIC ASYLUM, SINGAPORE.

FOR years past beri-beri has been endemic in the Singapore Asylum, defying all efforts to effectually stamp it out. 50 per cent. of the total deaths in 1896 were due to this cause alone, nearly 60 per cent. in 1897, and up to the end of June in the current year there have been 129 cases out of a daily average number of 228 resident patients with 25 deaths. Though the disease occurs principally in the damp, low-lying, ill-ventilated wards of the lower levels, no part of the asylum is free from cases, and though it is most widespread during the rainy periods, yet it crops up all the year round. The large majority of cases have been, in the first instance, of the so-called moist variety of beri-beri—viz., that in which there is no tenderness of the calves or forearms, no hyperæsthesia or anæsthesia so far as one can make out (but the symptoms connected with sensation are always difficult to determine among the insane), no muscular atrophy—in fact, no obvious neuritis, but in which there is considerable general or localised œdema with great weakness and loss of knee-jerks, the superficial reflexes being usually unaffected. The œdema frequently clears up in the course of a few weeks under treatment by free purging, with diuretics (especially digitalis) and full doses of strychnine, but unfortunately relapses nearly invariably occur, patients only recovering to be again struck down in from a month to a few months' time, and so cases may continue for a year or even longer. But sooner or later serious symptoms supervene, these being lung œdema, hydrops pericardii, cardiac failure, functional murmurs, reduplicated heart sounds, epigastric tightness with præcordial and substernal pains, dyspnœa, and vomiting, this latter symptom being generally of grave import. It should be noted that the degree and extent of the œdema are not proportioned to the gravity of the attack; patients completely water-logged often make good recoveries, while others who are but slightly swollen frequently die.

The degeneration which is found in the nerves of the extremities in patients who have suffered from the so-called dry or paralytic beri-beri is not to be found in many of the cases seen here, and at one time I, with others, was somewhat in doubt as to whether these were really cases of beri-beri, but noticing the fact that many of the patients soon after losing all or some of their œdema developed all the symptoms of peripheral neuritis led me to wonder whether other nerves than those commonly affected were not involved in some cases, and I was strengthened in this conjecture by a paragraph in a short paper on beri-beri by Dr. M. Simon, published in the *Journal of the Straits Medical Association* for 1891–92, in which he states his impression that the œdema may be caused by neuritis of the vaso-motor nerves. I commenced therefore to examine some of the nerves of the sympathetic system. I have now examined a large number of nerves removed from patients dying from the disease and have met with many cases in which all the peripheral nerves were healthy, but in which some or all of the following nerves were markedly degenerated — viz., the phrenic, branches of the cardiac and pulmonary plexuses, the splanchnics, branches of the solar and renal plexuses, branches to the mesentery, and vaso-motor branches to the aorta, renal, splenic, and tibial arteries. In no case of death from beri-beri have I failed to find degeneration of either the phrenic, pneumogastric, or branches from the cardiac plexuses, showing, it seems to me, definitely that death invariably occurs in the disease from implication of some of these nerves. The phrenic is the nerve most frequently involved.

Many exceedingly fine fibres are often to be noticed in carefully teased-out specimens of sympathetic nerves and I have considered these to be degenerated Remak's fibres, the sheath only remaining, and in this I agree with Dr. von Tunzelmann, who has expressed a similar opinion in an interesting paper on Beri-beri published in THE LANCET of Dec. 22nd, 1894. Other Remak's fibres show a proliferation of their nuclei probably pointing to commencing disease. Fibres not quite so fine are also to be noticed among medullated fibres from peripheral nerves which have undergone advanced degeneration and are probably collapsed Schwann's sheaths. In one case which had been for a long time prior to death affected with peripheral neuritis I found in the peroneal nerve a new fibre passing through an old nerve fibre sheath showing cessation of degeneration and recovery in progress. One patient under my care who has been paraplegic for over a year is now commencing to walk.

It may be mentioned that many examinations of blood from beri-beri patients have failed to show the bacillus which Pekelhäring and Winkler claim to have discovered, and unfortunately cultivations from the blood, and after death from the spleen, stomach, nerves, and other organs, have as yet given no useful results in my laboratory. Examination of blood with Gowers's hæmacytometer has shown the corpuscular richness to be normal in nearly every case, whilst the hæmoglobinometer has indicated in every case examined a deficiency of from 15 to 20 per cent. of hæmoglobin. Control experiments were made upon healthy persons living under the same surroundings.

In 125 necropsies of patients dying from beri-beri I found the average weight of the heart to be 13·37 oz., the right side in nearly every case being much enlarged; over the same period of time 204 hearts from patients who had died from other diseases were examined and they averaged just under 9 oz. In the 125 cases of beri-beri referred to the

Digitized by Google

spleens averaged 9·27 oz. in weight; the spleens of the 204 other cases averaged 6·28 oz. The kidneys and liver were sometimes, but rarely, congested. In the same 125 cases of beri-beri I found œdema of the lungs (usually to a slight extent) 78 times, hydrops pericardii (varying from 1 oz. to over half a pint) 86 times, hydrothorax 10 times, and ascites 5 times.

Latterly I have been paying attention to the condition of the stomach and have found the lining membrane of that organ congested 31 times in 57 cases post mortem, in most of the cases intensely congested, especially on the ridges of the corrugations. In 4 cases there were blood-clots present in the stomach, possibly due to the persistent vomiting, from which all had suffered prior to death.

In conclusion, it seems to me that the degeneration of the peripheral nerves in the paralytic cases and of the sympathetic, phrenic, and vaso-motor nerves in the moist cases is the cause of the obvious symptoms of beri-beri; that mixed cases are most common; and that beri-beri is a most recoverable disease so long as the pneumogastric, phrenic, and branches from the sympathetic ganglia in the neck are unaffected, but that when these nerves, all or any of them, once become attacked death is imminent.

I have to thank Mr. H. J. Gibbs, assistant medical officer, for much assistance in preparing a very large number of the microscopical specimens.

Singapore.

UTERINE HÆMORRHAGE AS AFFECTED BY THE CLIMATE OF ALTITUDES.

BY SEPTIMUS SUNDERLAND, M.D.,

PHYSICIAN TO THE ROYAL HOSPITAL FOR WOMEN AND CHILDREN, LONDON; PHYSICIAN TO THE ROYAL MATERNITY CHARITY OF LONDON.

CHRONIC bleeding from the uterus is oftentimes so difficult to overcome that one grasps at any hopeful plan of dealing with it satisfactorily. I have therefore thought it necessary to bring to the notice of the profession the strikingly beneficial, though temporary, effect of a high altitude in three cases of obstinate menorrhagia, which was recently forcibly brought to my notice.

A patient, aged thirty-nine years, with chronic enlargement of the uterus causing severe menorrhagia, for which I have frequently prescribed during the past few years, was sent by Dr. Symes Thompson to winter at St. Moritz (about 5800 ft. above sea-level) in 1896–97 on account of contraction of a lung caused by influenzal pneumonia. She was accompanied by her daughter, aged thirteen and a half years, who had been under my care for several months for the menorrhagia of puberty, which was with difficulty kept in check by drugs.

CASE 1.—The mother when she first came under my notice four years ago had for some years been obliged to use as many as 40 sanitary towels at each period, and in addition suffered from irregular attacks of hæmorrhage. Treatment abolished the latter and reduced the periodical flow, which, however, had always remained excessive, as many as from 25 to 30 towels being necessary at each period. During the three and a half months passed at St. Moritz three periods were seen; their duration was shorter, there were fewer clots, and the flow was diminished in quantity about one-half, only from 12 to 14 towels being worn.

CASE 2.—The daughter's menstrual function had begun six months before leaving for the Engadine. The periods had been very profuse with a fortnight's interval between them and had lasted five days, about 15 towels being worn at each flow. During her stay at St. Moritz there was an interval of a month between the periods, which lasted only four days instead of five, and the quantity was reduced to about one-half.

So far so good, but after their return to England at the end of March the periods returned both in mother and daughter in the same quantities and with the same frequency as before. Drugs, however, have now diminished the quantity in the girl.

CASE 3.—A patient who suffers from climacteric menorrhagia, for whom I have prescribed on several occasions during the summer of 1897, has recently returned from a stay of five weeks at Arosa (altitude about 5500 ft.) whither she accompanied her son, who had been sent there by his medical attendant. During her stay at Arosa she had one period which lasted four days instead of the usual time, seven or eight days. She states that she lost only about half the quantity of blood which she had been in the habit of losing during the previous fifteen months and that instead of having repeated sudden gushes there was a steady flow throughout.

I have not been able to find any recorded statement of the usual effect of a high altitude on chronic uterine bleeding, and Dr. Holland of St. Moritz, under whose care the first two patients were placed during their stay, has favoured me with the information that he has made no special observations on this point. But the marked diminution in the amount of the menstrual flow in these three cases raises the question whether residence at a high altitude should not be recommended in certain cases of chronic uterine hæmorrhage where ordinary methods of treatment, including curetting, are of no avail, and in which it is important to check the hæmorrhage in order to spare the patient the more serious operation of extirpation of the ovaries or of the uterus. There are many cases of uterine hæmorrhage in debilitated subjects, especially from fibroids, in which the risk of a major operation is dreaded by some surgeons as much as by the patient, and it is for such that I myself in future shall feel disposed to advise residence for a time at a high altitude. I would also suggest a trial in menorrhagia due to subinvolution of the uterus after childbirth or miscarriage which do not respond to treatment or curetting. Sufferers who can bear the expense would be glad to avail themselves of the chance of relief afforded by such a change of climate, and it is possible if benefit be experienced from a short stay that a prolonged residence might produce a curative effect which was not found in the three cases which I have related. At any rate, even a temporary cessation from the draining and debilitating sanguineous flow would improve the anæmia and consequent feeble condition of such patients and give a little time for recuperation of strength and health which would assist them materially to bear their ailment, even if it should recur on returning to their ordinary place of residence. Further, the attendant anæmic state would be improved because both the number of red blood-corpuscles and the amount of hæmoglobin are considerably increased directly after arriving at an elevated region from a plain, probably (up to a certain point) in direct proportion to the altitude. The experiments of Paul Bert proved that the blood of animals living in high altitudes absorbs more oxygen than that of similar animals living at ordinary elevations, and successive experiments of Müntz, Viault, Egger, Mercier, and Miescher have gradually proved the facts which I have just stated with regard to the increase of red blood-corpuscles and hæmoglobin.

It will be interesting to determine whether the highest elevations available in Great Britain can be made use of to any extent in such conditions, and I believe they may. In seeking for a rational explanation of the causes of the lessened menstruation in the cases I relate it must be conceded that a low temperature was certainly one important factor in diminishing the amount of the menstrual flow. I have frequently noticed that many women menstruate less in winter than in summer, and we know that "some English-women of feeble development menstruate in summer only, and others too freely in hot countries, though not at home" (Robert Barnes), while some menstruate in hot countries and not in England. And since the temperature falls in ascending mountains about one degree Fahrenheit for every 300 feet (with certain exceptions in connexion with situation, shelter, &c.), I consider that it is certainly worth while trying such elevations in our own country for many patients who cannot bear much expense and do not care for exile to more elevated localities abroad, especially for those who habitually reside in moist, relaxing, and low-lying neighbourhoods. These moderate elevations would be also worth trying for numerous nervous and excitable patients who cannot reside at a very high spot without suffering from distressing nervous symptoms. In selecting such a place in Great Britain an elevated region with a low mean temperature should be chosen where the air is as free from moisture as possible and the soil well drained and dry, for in addition to a low temperature as a factor in the diminution of the flow in the cases which I have related one must conclude that the dry, tonic, and bracing climate had a beneficial effect by improving the general condition of the patients. Possibly this bracing effect may also act through

Digitized by Google

the nervous system, controlling and regulating menstruation.

Whether the improvement in the quantity and quality of the red blood-corpusules (which I have already referred to) caused by residence at a high altitude, had any effect or not in preventing free exudation of blood from ruptured or unruptured capillaries of the uterine mucous membrane it is not easy to determine. One might imagine this to be the case, remembering that on descending to plains after residence on mountains the red blood-corpuscles in human blood diminish again in number and quality (though usually only to the normal standard) and that in 2 of the cases under consideration the menorrhagia recurred soon after the patients returned home. We may, I think, at least assume that during residence at a high altitude the muscular tissue of the uterus and the walls of the uterine capillaries and small veins become firmer and less liable to rupture, in common with the increased nutrition and generally improved condition of all the tissues of the body; also that there is less venous congestion, owing to the more frequent pulsations of the heart and to the better tone and contractile force of the heart and of the arteries supplying the uterus, and to improvement in the whole circulatory apparatus.

But apart from all these causes I would suggest that the lessened barometric pressure which obtains at a high altitude may have an important effect in warding off and in diminishing hæmorrhages. I have not been able to find any written opinion on this point, but Dr. Theodore Williams in his book on "Aerotherapeutics" gives the results of experiments which he once made on the use of compressed air-baths in phthisis. His results appear to show that the compressed air-baths are not beneficial in cases complicated with hæmoptysis. He quotes 2 cases in which hæmoptysis came on during the bath and 4 cases in which hæmoptysis came on during the treatment. Dr. E. Hugh Snell in his book on "Compressed Air Illness" gives some instances, reported by various observers, of hæmoptysis, epistaxis, and congestions of various organs of the body occurring in men during or directly after working in diving-bells or in "caissons" (these latter are cylinders used for the foundation of piers and bridges in which two, three, or four atmospheres are compressed into one); also in tunnelling and excavating when compressed air is used to keep out water, hæmoptysis, epistaxis, and congestions have been noted. In a most interesting article contributed to the *British Medical Journal* (in 1896 I believe) Dr. Thomas Whitelaw of Edinburgh stated that he "had come to the conclusion that there is a marked affinity between a high barometer and hæmorrhages of various kinds, especially when the blood-vesssls are not in a healthy condition," and he gives sufficient evidence to be impressive, quoting various cases of hæmorrhage occurring on days when the pressure of the atmosphere was unusually high.

The writings and observations of these gentlemen support my impression that the low atmospheric pressure at an altitude may be an important factor in the prevention of certain hæmorrhages from the uterus, though the exact explanation is not easy to determine. As an example of the lowered atmospheric pressure at altitudes I give the following. Assuming the barometer to stand at 30 in. at sea-level the corresponding reading at an altitude of 5,800 ft. would be about 24 in., therefore about one-fifth of the weight of the atmosphere would be removed. Roughly speaking, we must deduct 1 in. from the sea-level reading for every 1000 ft. of altitude, a very slight correction being made for the difference in temperatures.

Now, in seeking for an explanation of the lessened hæmorrhage due to any possible change in arterial tension, one finds that the careful experiments of Fraenkel, Geppert, and Paul Regnard appear to prove that there is no appreciable change in arterial tension during residence at a high altitude. Personally, I think there must be slight variations in arterial tension (probably diminutions) occurring during the first few days which may have escaped notice. How, then, can we account for such a beneficial effect on hæmorrhage being due in some measures to the diminished atmospheric pressure? I think that possibly the diminution in the weight of the superimposed column of air on the surface of the abdomen and in the lungs may act by lessening the pressure on the internal abdominal organs and large veins, thus allowing a more free flow of blood through the large veins and portal system and diminishing uterine congestion. Dr. Paul Regnard says that hepatic congestion and hæmorrhoids are improved at a high altitude, and this he attributes to improvement in digestion; perhaps diminished pressure on the abdominal organs and large veins may also account partly for this; also, indirectly owing to diminished air-pressure (on account of the smaller quantity of oxygen contained in the air of high altitudes), during the first week of residence at an altitude the pulsations of the heart and the respirations are quickened and then gradually fall to the normal and the quantity of rarefied air also which enters the lungs is increased but falls gradually to the normal after the first week. Now, books on physiology teach that the acts both of inspiration and expiration are favourable to the venous circulation, assisting the flow of the venous blood into the heart; therefore, assuming this latter to be correct, I consider that the increased respirations which always occur at high altitudes should materially assist in relieving congestions of the pelvic and abdominal organs and be of benefit in preventing uterine hæmorrhage.

This note may help to dispel from the minds of some medical men the fallacy—which is fairly common—that a high altitude is provocative of hæmorrhages. Dr. Theodore Williams with his large experience has found high altitudes especially beneficial in hæmorrhagic phthisis. Haller and others have conclusively shown by carefully handled and criticised statistics that hæmorrhages from the lungs of phthisical patients are much less common on mountains than on plains. Dr. Paul Regnard of Paris, in his fascinating book on "La Cure d'Altitude" deprecates the common idea that the lessened air-pressure produces hæmorrhages from the air-passages and he gives excellent reasons to explain the very rare hæmorrhages from the nose and ear which occasionally occur in healthy mountain climbers.

In conclusion, therefore, considering the evidence which I have brought forward of (1) Dr. Theodore Williams's experiments, (2) Dr. Snell's writings and careful collection of facts, (3) Dr. Whitelaw's observations, (4) the scarcity of hæmorrhages from the air passages both in healthy mountain climbers and of phthisical patients (as proved by various authors), in conjunction with (5) my own observations of the decrease of menorrhagia in the cases I have related, I will say that I feel justified in believing for the present (1) that a high dry climate is beneficial to certain cases of chronic uterine hæmorrhage which do not respond to ordinary treatment and that, if practicable, residence at a high altitude should be tried for as long a period as possible in cases where operation is not absolutely necessary or is inadvisable from various reasons or would prove unusually dangerous; (2) that a high altitude would probably be found useful in certain hæmorrhages and congestions other than pulmonary or uterine; and (3) that in addition to other causes which produce the effect of diminishing uterine bleeding at a high altitude the lessened air pressure is an important aid.

ADDENDUM.

CASE 4.—Since writing the above I have within the last few days seen a lady suffering from a bleeding fibroid tumour who has consulted me occasionally during the past three years. She lives in a moist, relaxing neighbourhood in a southern county, but she passed the latter part of September and the whole of October (in 1897) in a very high part of Yorkshire. During that time she had one period and she reports that she was much surprised to find that there was a very marked decrease in the amount of the flow.

This encourages me to suggest more strongly that trial should be made in such cases of the moderate elevations at our command in Great Britain, such as the available parts of the Kent chalk hills, Malvern, Hindhead, Grayshot, Buxton, Harrogate, Llandrindod Wells, and many other localities. Possibly a permanent residence at such places might materially alter the future progress of some fibroid growths in which one fears a rapidly unfavourable issue. I hope to bring forward later other notes which I am collecting on the effect of climate on menstruation.

Cavendish-place, W.

PLYMOUTH INFECTIOUS HOSPITAL.—At the meeting of the Plymouth Board of Guardians held on Oct. 4th the alleged mismanagement of the Borough Infectious Diseases Hospital was further considered and a report of the Visiting Committee was adopted which vindicated their action and protested against the strictures of the hospital sub-committee of the town council as being uncalled-for and out of place.

SOME FURTHER NOTES ON THE USE OF BROMIDE OF STRONTIUM IN EPILEPSY.

BY ANTONY ROCHE, M.R.C.P. IREL.,
PROFESSOR OF MEDICAL JURISPRUDENCE AND PUBLIC HEALTH IN THE CATHOLIC UNIVERSITY MEDICAL SCHOOL, DUBLIN; EXAMINER TO THE ROYAL UNIVERSITY OF IRELAND.

IN 1894, and again in 1896, I published some notes, with cases, on the use of the bromide of strontium in epilepsy. I have many of the cases then mentioned still under my observation, with a considerable number of others. Perhaps therefore some remarks founded on a more extended experience in the use of this bromide may be of interest to the profession. Unfortunately I cannot give the results in all my cases, as some of my patients communicated with me only by letter, and I am therefore unable to follow the course in all. In the majority of cases, however, I have been able to learn the results of the treatment.

I have not met any case in which the bromide of strontium given in the doses and method I will mention has failed to diminish the number of the attacks. In many instances there has been no return for periods extending to two, three, and even four years. Some of these cases may be considered "cured"—that is, that there will be no return of the attacks when the medicine is permanently left off. I cannot say definitely that this is so, for the reason that I always recommend the patients to continue the medicine, even though there has been no return for a long period. I do this all the more as I have not found the continued use of bromide of strontium to be followed by any bad consequences, and many of the patients have been taking 1 drachm daily without intermission for more than three years without any complaint. In this respect the strontium salt has an immense advantage over the potassium salt, which has frequently produced serious physical and mental changes when continued for long periods. Moreover, patients taking bromide of potassium frequently suffer from intense depression. Several of my patients were obliged to leave it off owing to this; in fact, several expressed their feelings by assuring me that they would rather suffer from the fits than from the depression produced by the medicine. I have not noticed this at all in those using the bromide of strontium. The potassium, too, is poisonous in large doses; the strontium is not. On this point I may quote one of the most recent authorities, Dr. Dixon Mann, who in the second edition of his excellent "Manual of Medical Jurisprudence" says that "strontium salts cannot be regarded as poisonous." I have myself given 3 drachms daily for weeks without any unpleasant symptoms. I consider, therefore, that the strontium salt excels that of potassium in being more efficient and in not being followed by dangerous consequences when it is continued over a lengthened period; and as it is not poisonous it can be given in as large a dose as may be required to control the attacks.

In my earlier cases, being influenced by the remark of Brown-Séquard that the combined bromides were more useful, I gave the bromide of strontium combined with one or more of the other bromides, but for a long time I have given that of strontium alone. I usually commence the treatment by ordering half a drachm night and morning in some vegetable tonic infusion. Should that dose not control the attacks I rapidly increase it till I have found the quantity which will suit the individual case. I direct the patient to take 30 grains at once in those cases where there is any warning of the attack and to repeat this every hour if required. By this means I have no doubt the attack has been frequently prevented. I may repeat that in my experience in order to get the full benefit of the medicine I have found it necessary to give it in large doses and to continue it for a long period. Since my first communication several members of the profession have written to me saying that in their cases they have not found the same good results. I invariably find that in these cases the dose given has been too small and consequently that my practice has not been followed. I need not say that each case requires to be studied on its own merits and any exciting or predisposing cause lessened or removed. I do not think it necessary to go any further into this question, as these notes are not upon the general medical or surgical treatment of epilepsy, but upon a special medicine, nor need I give my experience in the use of any other of the many remedies proposed. Many of these I have tried, but none have given me the same good results as I have found by the use of bromide of strontium.

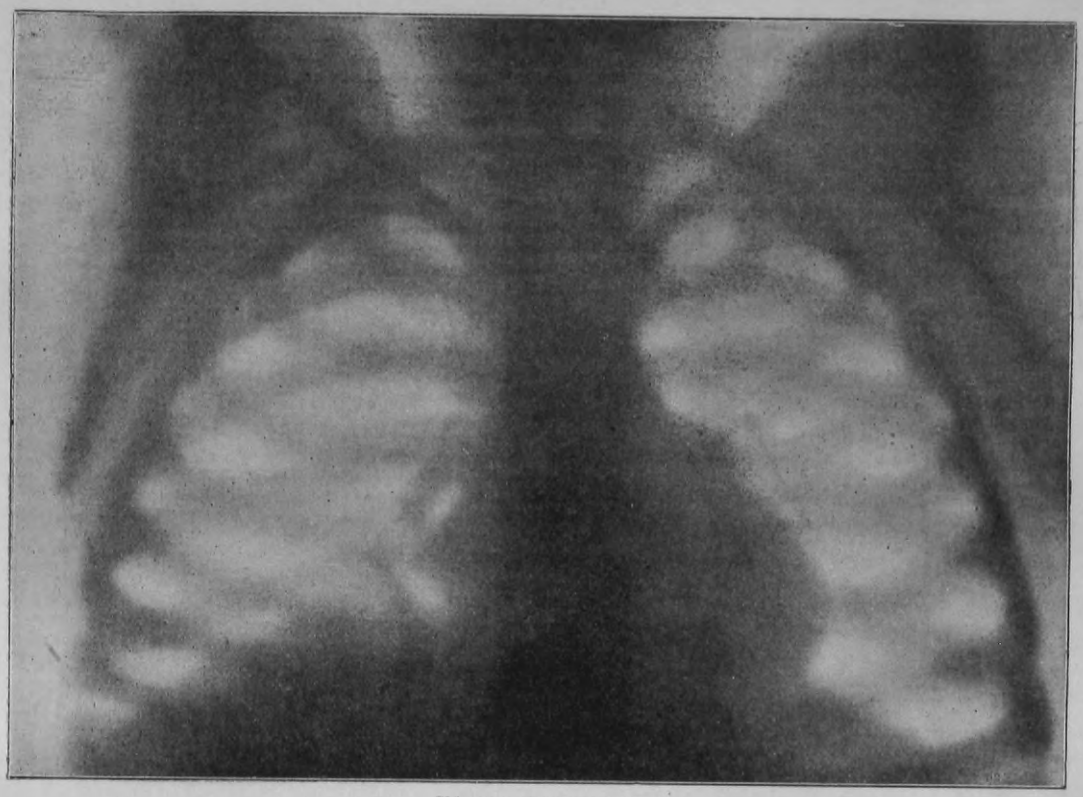
I should say, however, as I have more fully explained on a former occasion, that I regard the question of diet as one of much importance. I direct my patients to restrict themselves to fish and vegetables, and I generally find no great difficulty in having my orders carried out. When the attacks diminish in number, if I am pressed to do so I allow the more easily digested meats twice or three times in the week.

I propose to return to this subject in a subsequent communication and to give details of some of my cases.

Dublin.

THE X RAYS IN DISEASES OF THE CHEST.

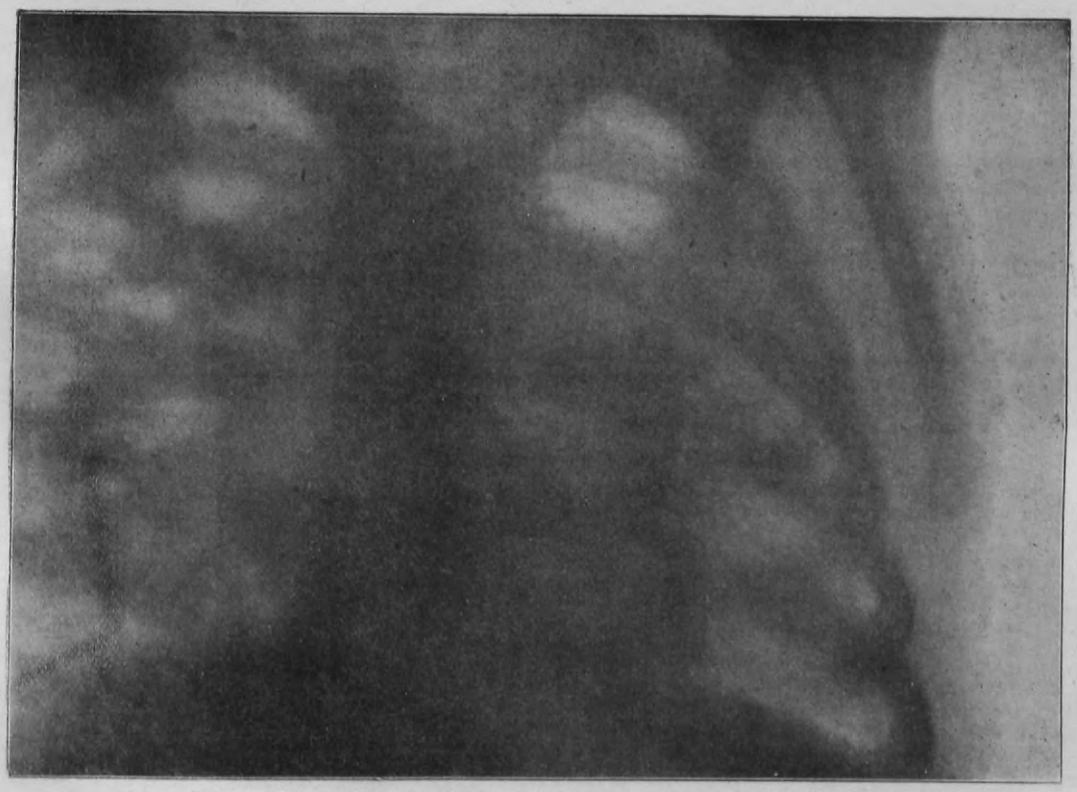
BY HUGH WALSHAM, M.A., M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST; ASSISTANT MEDICAL OFFICER IN THE ELECTRICAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL; AND CLINICAL ASSISTANT TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.



THE experience of the last three years has been quite sufficient to prove beyond question the usefulness of Professor Roentgen's discovery to the surgeon. I venture to think, however, that a systematic application of the rays to the diagnosis of chest disease will prove of equal value to the physician. From some cause the x rays have up to the present time not been so extensively used by the physician as they have by the surgeon, and yet they are capable of showing very distinctly pathological conditions within the chest. Unfortunately at present we have not the apparatus necessary at the City of London Hospital for Diseases of the Chest to examine patients; but what little I have been able to do thoroughly convinces me of their great value in chest disease, more especially in diseases of the lung. This, I think, will be quite apparent from an examination of the two accompanying skiagrams.

The first (Fig. 1) is from the chest of a perfectly healthy boy, aged nine years. It is seen at once that both lungs in a healthy condition are perfectly transparent to the rays from apex to base, allowing the posterior portions of the ribs to be clearly seen. Some slight shading will be seen on each side corresponding to the position of the larger bronchi, but with this exception the healthy lung is quite transparent to the rays. Whether this transparency continues with advancing life I am not quite sure, probably it does not. I think that as life advances the lung becomes somewhat less transparent, but this of course affects the whole lung equally. If we now turn to Fig. 2 we see at once that there is a great difference. The skiagram is from the chest of a boy, aged fifteen years, who came under my care when I was in charge of Dr. Harrington Sainsbury's wards during the past summer. Physical examination of the chest gave signs of a cavity at both apices. On the left side the physical signs of the cavity extended from the apex downwards to the level of the third rib. I was therefore much surprised on examining this patient with the fluorescent screen to find that the cavity was, comparatively speaking, a small one, certainly not extending so far downwards as auscultation led one to suppose. The cavity at the right apex was also smaller than one would have thought from auscultation signs. The cavities are well marked in the skiagram as two more or less round clear spaces surrounded by a dark shading. On looking at the lower parts of the lungs we see varying degrees of transparency mixed up with tracts of shading. This shading corresponds, no doubt, with consolidated lung tissue, but partly perhaps with pleural adhesions.

I have quite lately had the opportunity of taking a skiagram of a pleural effusion (serum). It shows a uniform darkening of the whole of the affected side, quite unlike the mottling of the lung in tuberculosis. This darkening stands out in marked contrast to the transparent lung tissue on the unaffected side. The diaphragm also stands lower on the affected side. I think it is very probable that with the aid of the x rays one may be able to distinguish between serum



Digitized by Google

and pus, but at present I have not had an opportunity of making the observation. I think it is doubtful if the rays can enable one to distinguish between consolidation of the lower lobe of a lung and an effusion into the pleura.

Early cases of tuberculous consolidation of one or other apex display its presence by a dark shading at that apex, probably before physical signs become apparent. Enlarged bronchial glands, especially in children, are, according to Professor Bouchard and Professor Claude, easily distinguishable by the x rays, but of this I have had no experience. It does not appear likely that the x rays will be of much use in the examination of the heart. True, they will show enlargement of the organ, but of this we have abundant proof without their aid. I think it is in lung disease, especially in tubercle of the lung, that they will be found of great use both in diagnosis and prognosis. Both the accompanying skiagrams were taken by myself in the electrical department of St. Bartholomew's Hospital.

Harley-street, W.

NASAL OBSTRUCTION AND EAR AFFECTIONS.

BY MAYO COLLIER, M.S. LOND., F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON TO THE NORTH-WEST LONDON HOSPITAL.

THE admitted difficulty in treating affections of the middle ear associated with deafness, tinnitus, or chronic discharges and the unsatisfactory results which follow in many cases the usual methods of treatment are due in a large measure to an improper understanding of the relationship and bearings of nasal obstruction as a primary cause or starting-point of most aural affections. If this be so it naturally follows, seeing that the study of aural diseases and their treatment dates back to a period long before a nasal speculum was dreamt of and long before a line of literature recorded a single observation or examination of the nose, that a minute and careful study of affections of the nasal chamber is a necessary preliminary to a proper understanding of most of the commoner affections of the ear.

"Throat deafness" is a well-recognised and significant term used and understood by professional and non-professional persons alike to indicate a state of things which may be literally interpreted as Eustachian obstruction the result of catarrh and swelling of the orifice of the Eustachian tube, usually a sequela or extension of nasal catarrh and consequently of nasal obstruction. Simple obstruction of the orifice of one or both Eustachian tubes following nasal catarrh is the starting-point or antecedent of a very large percentage of the commoner affections of the ear which make themselves apparent to the patient, as deafness, noises in the head, and "running" from the ear.

It is perfectly obvious that if the antecedent condition of Eustachian obstruction and catarrh were effectively treated and its cause was removed the more lasting and grave affections of the middle ear would be prevented and their subsequent treatment rendered unnecessary. I will enlarge my proposition and go one step further. Given chronic and well-marked affections of the middle ear set up and induced by an original Eustachian catarrh and obstruction no permanent improvement can be hoped for or attained unless the *fons et origo mali*, the Eustachian obstruction, and its *causa causans*, the nasal obstruction, be removed.

I never find chronic deafness with or without noises in the head and discharges from the ear unassociated with nasal obstruction and I seldom have failed even in the most chronic and intractable cases to attain some degree of improvement either in the deafness, tinnitus, or discharge by removing the cause of the Eustachian obstruction—i.e., by ventilating the nose. To some persons it may not be apparent how an obstructed nostril can cause Eustachian obstruction and catarrh.

During inspiration the free ingress of air is requisite to fill the chest cavity on expansion of the thorax. An obstructed ingress means rarefaction of the air in the chest cavity and the passages leading thereto. During impeded nasal respiration the air in the post-nasal space is consequently of lesser density than the outside air. As a result of this the intravascular and extravascular pressures are not equilibrated (as in dry cupping) and swelling of the parts with engorgement of the vessels takes place. This vascular engorgement and consequent swelling of the orifice of the Eustachian tubes involves obstruction to the free passage or ingress of air to the tympanic cavity as well as often an extension of the catarrhal process through the Eustachian canal to the tympanic cavity.

To follow this apparently simple catarrh a step or two further, the fact of obstructing the free inlet of air to the tympanic cavity causes a serious physical disturbance. The air present in the tympanic cavity becomes shortly absorbed, causing a negative intra-tympanic pressure. This causes engorgement of the whole lining membrane of the tympanum, with possible and probable effusion into that cavity according to the degree of the vacuum. Added to this the unsupported drum-head is driven inwards by the unbalanced atmospheric pressure and deafness with or without tinnitus is the probable result. The sequence of trouble is not yet complete. The extension of the catarrhal process to the tympanic cavity may mean the introduction of certain pathogenic organisms and the consequent more acute state known as abscess of the middle ear.

The formation of pus is usually associated with pain in the ear, severe in character; high temperature with or without delirium; and sooner or later bursting of the drum-head with discharge of pus from the external ear.

The vista of possible consequences of our original Eustachian obstruction from catarrh is not yet obscured. The immediate result of an acute abscess of the middle ear is usually perforation of the drum-head with cessation of the acute symptoms and relief to the patient. Not so always with infants and children, convulsions and death are a common termination of the acute stage.

The after-stage of a tympanic abscess may be short or long. Healing of the perforation may take place, to re-open with the next cold in the nose and throat and again discharge, lapsing ultimately into a chronic ear discharge. The chronic ear discharge may, but rarely does, end in spontaneous cure. More often a chronic discharge from the ear is kept up for many years and either ends in death from abscess of the brain or septicæmia from infection of the lateral sinus, but more often in caries of the petrous bone and impairment of the general health and death from some indirect cause.

In drawing this sketch of a simple cold in the nose leading to throat and post-nasal catarrh and the consequent Eustachian obstruction I have not exaggerated in the smallest degree. My object is to impress upon those who have the care and the treatment of these cases that simple and appropriate treatment applied to the original catarrh and obstruction would prevent and save this long sequence of aural troubles. An astringent and antiseptic wash to the nose would restore nasal respiration, relieve Eustachian congestion and obstruction, and permit a free ingress of air to the tympanic cavity. In chronic cases of deafness with tinnitus and discharge due originally to Eustachian catarrh and obstruction the same treatment applies, and is absolutely essential and a *sine quâ non* of any permanent improvement and success in these cases. A wash followed by the galvano-cautery or other methods of ventilating the nose is the first step in treating these chronic aural affections. Then and then only will the Politzer bag and the Eustachian catheter avail anything.

Harley-street, W.

GIFT OF A WATER-SUPPLY.—Mr. D. R. Scratton on Oct. 6th presented a water-supply to the village of East Ogwell, near Newton Abbot, Devon. The cost of the gift is about £3000. Mrs. Scratton turned on the water with a golden key presented by the villagers. The day was observed as a general holiday and Mr. Scratton was presented with an illuminated address of thanks.

CLINICAL SOCIETY OF MANCHESTER.—At the annual meeting of this society, held on Oct. 4th, the following office-bearers were elected for the session 1898–99:—President: Dr. A. Hill Griffith. Vice-presidents: Dr. E. S. Reynolds and Mr. E. Roberts. Treasurer: Dr. C. H. Braddon. Secretary: Dr. T. A. Helme. Librarian: Mr. J. W. Smith. Auditors: Mr. C. F. H. Kitchen and Dr. T. Porter. Committee: Dr. Alfred Brown, Dr. R. Crean, Dr. J. Daniel, Dr. J. W. Hamill, Dr. T. Harris, Dr. J. Holmes, Dr. T. N. Kelynack, Dr. M. P. Ledward, Mr. H. Lund, Mr. C. T. B. Maisey, Dr. E. T. Milner, Dr. R. T. Parkinson, Mr. J. E. Platt, Mr. J. Rust, and Mr. F. H. Westmacott.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procœmium.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

A CASE OF HYDATID CYST OF THE LUNG.

(Under the care of Dr. F. G. PENROSE and Mr. T. H. KELLOCK.)

HYDATID of the lung, though fairly frequent in some parts of the world, is distinctly rare in this country. The diagnosis is often far from easy, though an examination of the expectoration, should there be any, may in some cases prove of value. The prognosis in cases not operated on is very grave and the mortality has been given as two out of every three. In patients on whom an operation has been performed the death-rate is much less. Lopez gives only 5 deaths in 32 operations and Reclus[1] gives it as 2 cases out of 11. There can be no doubt that incision of the lung is the correct operation to perform and it is seldom accompanied by hæmorrhage of any moment. The alternative method, aspiration, was formerly employed to some extent, but in no small number of the cases the cyst has burst into the lungs as a result of the aspiration before much fluid had drained away by the cannula, so that the patient has been practically drowned in the hydatid fluid.

A thin, anæmic girl, aged five years, was admitted to the Hospital for Sick Children, Great Ormond-street, on March 21st, 1898, complaining of cough and pain in the left side of the chest. There was a history of phthisis in the mother's family. The patient was born in Melbourne and was brought to this country when she was three years old; she was breast-fed for two months and was then given cow's milk. She had always been delicate, suffering from colds and cough; when she was one year old she had an attack of measles, when two years old whooping-cough, when three years old meningitis (?), and when she was four years old she attended a hospital as an out-patient on account of her chest. Seven weeks before admission she had influenza, since which the mother had noticed that she was more pale, coughed a good deal, and complained of pains in the left side, right shoulder, and legs. A month later the mother's account was that a medical man had told her that the left lung was solid, but three weeks afterwards — i.e., one week before admission — he said that there was fluid in the left side of the chest. On admission the child was in no distress, but complained of occasional pain in the left side. The temperature was 99·8° F. and the respirations were 30. There was no obvious difference in the shape or in the measurements of the two sides of the chest. The respiratory movements were better at the lower part of the right lung than of the left. At the lower part of the left lung there was an area of absolute dulness, the upper limit beginning at the sixth rib in the nipple line in front and sloping upwards to the fifth rib in the axilla; crossing the scapula at this level it turned suddenly downwards and reached nearly to the base of the lung two and a half fingers' breadth from the vertebral column. There was impairment of resonance below the fourth rib in front, hyper-resonance in the first two intercostal spaces, and a band of resonance at the extreme base below the absolute dulness. Tactile vocal fremitus was feeble everywhere, being absent over the dull area. The breath and voice sounds were weak over the impaired area, the former being absent and the latter feeble over the dull area. There was no ægophony or bronchial breathing. No fluid thrill was obtained; the thoraco-parietal glands were not felt. The heart was displaced, the dulness extending two and a half fingers' breadth to the right of the sternum; the sounds were abnormally conducted over the right side of the chest. There was a little impairment of resonance at the base of the right lung. Both the liver and spleen could be felt below the costal margin, but nothing else abnormal was detected in the abdomen. An exploring needle inserted into the dull area withdrew hydatid fluid. On the same evening, chloroform having been administered, a curved incision was made over the sixth and seventh ribs in the posterior axillary line; about 1½ in. of each of them were removed and the pleura was freely opened. Adhesions were found posteriorly and below the opening, but above and in front there were none. The presenting lung tissue was pale in colour and many vessels were visible on its surface. A few stitches having been inserted to unite the visceral and parietal pleuræ a trocar and cannula were introduced into the lung and clear fluid escaped. The opening was then enlarged and it was found to lead into the adventitious cyst which was of about the size of an orange and full of hydatid fluid, which, together with the true cyst which was found to be collapsed and empty, was removed. The edges of the opening were sutured to the parietes, the rest of the wound in the chest wall was closed by sutures at either end, the cavity was packed with cyanide gauze and a dressing was applied. It was noticed that the walls of the adventitious cyst in the lung showed no tendency to collapse when its contents had been removed. There was no hæmorrhage of any severity at any stage of the operation, which the patient bore fairly well. For three days after the operation retention of urine was a troublesome feature and had to be relieved repeatedly by the application of fomentations to the abdomen. The cavity showed no tendency to contract. There was very little discharge from it, but on March 25th it was noticed on dressing the wound that when the plug of gauze was removed some air and mucus came from the opening. On the 26th and 27th the child on three occasions passed about half an ounce of quite clear fluid from the rectum independently of defecation. Chemically this was identical with hydatid fluid, but no hooklets could be found in it. Rectal examination revealed nothing abnormal. On the 27th some air and mucus were still coming from the wound. The heart had returned somewhat towards the left, although there was no apparent alteration in the size of the cavity. On the 28th and 29th the patient passed a good deal of pus with the motions. The abdomen was quite supple and not tender, and she seemed to be altogether brighter and better. The liver was felt about two fingers' breadth below the costal margin, its surface being quite regular. After the 30th there was no more fluid or pus from the rectum, the patient gradually improved, and the cavity in the chest began to contract; there was a little air coming and going through the wound for a short time. On April 9th she developed measles, but this apparently in no way interfered with her recovery and when she left the hospital on the 26th the wound in the side had healed; there was a little falling in of that side of the chest as well as some straightening of the spine in the situation of the fifth, sixth, and seventh dorsal vertebræ. The liver was still somewhat enlarged, but no definite tumour could be felt in it.

Remarks by Dr. PENROSE.—I think that the most interesting point in this case is the fact of a discharge *per anum*, first of a clear fluid evidently hydatid on March 26th and 27th followed by pus in the fæces on the 28th and 29th. The most probable explanation seems to be that a second cyst ruptured somewhere into the lower part of the intestinal tract and subsequently sloughed away. It is well known that hydatid cysts are frequently multiple. Up to the present there is no evidence of the presence of any more, though there is no obvious cause for the persistent enlargement of the liver.

Remarks by Mr. KELLOCK.—The comparative rarity of the operation for hydatid cyst of the lung in this country makes me think that this case is worth recording. The operation itself was rendered easy by the fact of the cyst lying so near the surface of the lung that only a very thin layer of the latter had to be divided. The conditions found when this stage of the operation was reached had been rendered rather confusing by the puncture of the cyst; the adventitious cyst formed of condensed lung tissue was found to be full of fluid, the hydatid itself being collapsed and separate from the wall of the former. So little of the lung substance having been incised at the operation it was rather difficult to account for the occurrence and persistence of the aerial fistula. A noticeable feature in the after treatment was the

[1] La Presse Médicale, Oct. 19th, 1895.

Digitized by Google

length of time which the cavity in the lung took to close; it would appear that the wall of the adventitious cyst had become so rigid that it was able to resist for some time the expansile force of the surrounding lung tissue.

TEDDINGTON COTTAGE HOSPITAL.

A CASE OF CÆSAREAN SECTION; RECOVERY.

(Under the care of Mr. T. B. LUSCOMBE.)

THE case reported below is remarkable in that the unusual expedient was adopted of removing the head from the uterus by abdominal section after the rest of the fœtus had been delivered by the vagina and decapitation had been performed. It can be but rarely that such a method is justifiable, for as a rule if the pelvis and shoulders of the child have succeeded in passing through the mother's pelvis it is easy for the head to follow, unless by undue traction the aftercoming head has become extended. The result of the operation seems to have been very satisfactory.

On March 26th Mr. Luscombe was asked by Dr. Theodore Günther to see a case of protracted and difficult labour. The patient was thirty-one years of age and had had three previous confinements. The first labour was said to have been "a very bad one and the child had to be taken away in pieces." The two subsequent labours appear to have been uneventful, but she said that the children were small. The patient was anæmic and had a troublesome cough. Labour commenced on the evening of March 24th; there was a breech presentation, the child lying in the left dorso-anterior position. On the next day the membranes ruptured and the os uteri was fully dilated, but very little progress had been made. Mr. Hermann Günther also saw the patient. The fœtal heart sounds were distinctly heard. The pelvis was measured and was found to be 3 inches in the conjugate diameter. On the morning of the 26th the fœtus was a little lower, the pains were not strong, and some meconium was found in the vagina. As the patient was getting tired it was decided to bring down the legs with the view of accelerating matters and chloroform was given. The left leg was brought down and then with more difficulty the right leg. The body was now delivered, the shoulders giving much more trouble than the legs. To deliver the after-coming head traction on the body was of no avail. Jaw traction was tried with a like result. Then forceps were applied, but with a negative result. As the head did not seem to be abnormally large when grasped with the forceps it was thought that if decapitation were performed the manipulations with the forceps would be easier as more room and possibly a more advantageous grip would be obtained. This was done, but repeated efforts failed to extract the head. It was at this stage that Mr. Luscombe saw the patient at about 3 P.M. She was somewhat exhausted, the pulse was fairly good, and feeble pains occurred every few minutes. The uterus was in a condition of more or less tonic contraction and the chin of the fœtus had rotated on to the pubes. The neck was gripped by the os uteri, so it was not possible to make much examination internally. Above the pubes could be seen a swelling of about the size of a small orange—the outline of the distended bladder; behind and slightly above this the hard fœtal head and the placenta could easily be felt, and still higher there was a large semi-fluctuating mass filling the upper part of the uterus. This was afterwards found to be blood-clot. An attempt was now made to empty the bladder, but the chin was so firmly fixed upon the pubes that a catheter could not be passed into the bladder.

The surroundings of the patient were not suitable for any further operative measures, so it was decided to remove her to the Teddington Cottage Hospital with the object of placing her under an anæsthetic and if necessary to perforate and crush the head or perform Cæsarean section. At about 6 P.M. the A.C.E. mixture was administered. Mr. Luscombe was then able by external manipulation to push the head just far enough upwards to allow of a catheter being passed and about a pint of blood-stained urine was obtained. After further consultation with his colleagues who had not seen the case before admission it was decided that to alter the position of the head, without using unjustifiable force, would be practically impossible, and that the risk of abdominal section would be less than perforation and cephalotripsy. This opinion was probably strengthened by the good recovery in this hospital of the patient whose case was reported in THE LANCET of April 16th. After the usual cleansing of the skin, &c., Mr. Luscombe opened the abdomen along the linea alba. There was scarcely any hæmorrhage. The uterus was then opened by a corresponding incision, but the tissue was so soft and friable that it was not easy to avoid tearing it. As soon as possible the skull was grasped on either side over the parietal eminences with the fingers of each hand. It required some force to dislodge it and it slipped through the hands of the operator out of the abdominal incision. In the sudden escape of the head a rent occurred in the lower part of the uterus, about 2 in. long, to the left of, and at a right angle with, the previous incision. The placenta (which was not adherent) and a mass of blood-clot lying above it were then removed. There was moderate hæmorrhage for about a minute or two and the blood was allowed to escape through the vagina. The cavity of the uterus was irrigated with hot water until the bleeding had practically ceased and dusted with iodoform powder. The incision and the rent made by the sudden escape of the head were sewn up with silkworm gut sutures ½ in. or less apart; a few blood-clots and some blood-stained fluid were sponged out of the peritoneal cavity and the abdominal incision was closed with deep silkworm-gut and superficial horsehair sutures. In the lower part of the wound a piece of alembroth gauze was left for drainage and the dressing was completed with iodoform, alembroth wool, and a broad flannel bandage. The patient was then removed to bed. The fœtus was a male and on examining the head it was found to be larger than normal and well ossified; the fontanelles were obliterated, as the edge of one parietal bone overlapped the other to the extent of nearly ½ in., this being probably the result of pressure exerted by the forceps. The patient passed a quiet night, had no pain, but slept very little. She drank several teaspoonfuls of water and brandy (½ oz.) mixed with water. On the 27th the catheter was passed, the urine withdrawn being dark and thick. The temperature was 98° F. and the pulse was 100 and feeble. During the day she took chicken jelly (2 oz.) and brandy (1 oz.) mixed with water. In the evening she was restless and complained of abdominal pain. The gauze was removed from the lower part of the wound without disturbing the dressings. There was a very slight serous discharge. The catheter was passed and the urine was found to be much clearer. The temperature was 98·2° and the pulse was 96 and weak. The subsequent progress of the case has no special interest. The cough, without sufficient chest trouble to account for it, was the chief difficulty for the first few days, whilst later obstinate constipation supervened. The temperature and the pulse-rate were highest on the sixth day after the operation, being 101° and 104 per minute respectively. The patient did not seem to be ill on that day, and the rise in the temperature from 99° in the morning was presumably due to constipation, as the temperature did not again rise above 99°. The patient left the hospital recovered at the end of May.

Remarks by Mr. LUSCOMBE.—The result of this operation, following so soon after the other above referred to, and the present condition of both the patients, I venture to think prove that the risks to the patients from abdominal section were less than would have been incurred had any other method of delivery been resorted to and the treatment had, moreover, the advantage of avoiding the danger of lacerating the uterine or vaginal mucous membrane.

PAUPER CHILDREN IN PLYMOUTH.—At the meeting of the Plymouth Board of Guardians held on Oct. 4th it was decided to adopt the "scattered home system" for the pauper children in the borough. The details of the scheme have yet to be settled, but doubtless it will be on lines similar to those adopted by the Sheffield board.

FATAL CARRIAGE ACCIDENT.—Much regret is felt throughout North Devon at the death of Mrs. Joseph Harper, which occurred on Oct. 7th. Mrs. Harper was the wife of Mr. Joseph Harper, L.R.C.P. Lond., M.R.C.S. Eng., J.P., of Barnstaple, and she sustained an injury to the brain as the result of a carriage accident mentioned in THE LANCET of Oct. 1st, p. 891.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Annual Meeting.—President's Address.—Study of Dyspepsia.

THE annual general meeting of this society was held on Oct. 10th, the retiring President, Dr. SANSOM, being in the chair.

The balance-sheet was presented and showed that after the redemption of debentures to the amount of £200 an increased balance was present at the bank. Votes of thanks were passed to the retiring officers, and Dr. HECTOR MACKENZIE proposed, and Dr. CALVERT seconded, a very hearty vote of thanks to Dr. Sansom, which was carried by acclamation. Dr. SANSOM replied, and inducted his successor, Mr. Edmund Owen, into the chair.

An ordinary meeting was subsequently held, Mr. OWEN being in the chair.

The PRESIDENT delivered an inaugural address. He urged the Fellows to make more use of the library, which, among many other treasures contained fifteen leather-bound manuscript volumes, which formed the commonplace book of the Rev. John Ward, M.A., vicar and doctor of Stratford-on-Avon from 1662 to 1681. He studied practical anatomy at the "Barber Chyrurgeons' Hall" in Monkwell-street under Dr. Scarborough, the friend of Harvey, who gave demonstrations there on the bodies of persons executed for crime. Taking up his work in Stratford-on-Avon in the forty-sixth year after Shakespeare's death he must, both as vicar and doctor, have been told of many facts concerning the Bard by those who had been personally acquainted with him. What little he said in these memorandum books had been already seized upon by Halliwell Phillipps in his "Life of Shakespeare." One of the extracts is of undoubted biographical value: "I have heard that Mr. Shakspear was a natural wit without any art at all; hee frequented the plays all his younger time, but in his elder days livd at Stratford and supplied the stage with two plays every year, and for that had an allowance so large that hee spent at the rate of £1000 a year." And again: "Shakspear, Drayton, and Ben Jhonson had a merry meeting, and itt seems drank too hard, for Shakspear died of a feavour there contracted." In those days it was customary to call all obscure diseases "feavours," just as they are now called "influenza" or "neuroses." In this commonplace book Ward records that some man at Cambridge cured ague by injections into the veins "just as Mr. Wren did into the veins of a dog." He was not satisfied with Oxford as a school, leaving it for London for his clinical education, and quotes Sydenham to the effect that "one had as good send a man to Oxford to learn shoemaking as practising physic." Possibly he thought the teaching too speculative, for he wrote: "A schollar att Oxford applying himself to an elderly physitian of that university to know whether he was in a consumption or not, hee askt the schollar whether hee spitt blood or not? He answered negatively. 'Then,' said he, ''tis but a physick cough and I will warrant you from a consumption'; but three months after his body went to the wormes." He took a lively interest in practical pharmacy and said it would be an excellent thing for physicians to make up all their physic in troches. He insisted on the need of fresh air for children, advised the scraping of chronic ulcers, and gave a graphic account of subcutaneous tenotomy by a mountebank who "cutt wry necks by making an orifice with his launcet and lifting up the tendon for fear of the jugular veins, then by putting in his incision knife and cutting them upwards they gave a great snapp when cut. ..... When he hath cut it he bends the child's head the other way and so by constant bending it becomes straight." Subcutaneous tenotomy therefore was not altogether a modern invention. It had now had its day and was rapidly giving place to a less speculative treatment. Constant reference was made in Ward's diary to small-pox and its ravages, but in view of the "tremendous experiment" which it had just pleased the Government to make with regard to this loathsome disease Mr. Owen said he had not the heart to refer further to it. Government had indeed sown the wind, but when the reaping of the whirlwind came the plentiful harvest would, unfortunately, be composed of the innocent, helpless, and ignorant—the very people whom a civilised Government was most bound to protect. In concluding Mr. Owen said he hoped that the suggestion made in his oration eighteen months ago would be carried out and that the last meeting should be an unreported "surgical confessional evening" at which mistakes and failures only should be brought before the society.

Dr. ALLCHIN read a paper on Some Considerations Preliminary to the Study of Dyspepsia. He first of all referred to the need for a more careful nomenclature. He reminded the society that digestion took place in the whole course of the alimentary canal and not in the stomach only and that the term "indigestion" or its synonym "dyspepsia" should not be restricted to disorders of gastric digestion only. Schlatter's case of total excision of the stomach showed that it was not an essential organ and that the importance of the *rôle* of hydrochloric acid had been exaggerated. The immediate causes of indigestion might be grouped as follows:—1. Errors in quantity or character of the food. 2. Diseases of the digestive organs, either (*a*) structural, (*b*) due to impaired nervous control, or (*c*) abnormal blood or lymph-supply. 3. Improper bacterial action. 4. Defective absorption. 5. Abnormal intestinal excretory processes. After enumerating the "protean symptoms" of dyspepsia Dr. Allchin pointed out that one of the chief difficulties in studying the subject was that many totally different conditions gave rise to similar symptoms. He contended that an attempt must be made to base diagnosis on knowledge of the anatomy and physiology of the alimentary canal. No single symptom was diagnostic, but the association of symptoms was very significant. Dr. Allchin considered the use of the term "functional" dyspepsia as mischievous, believing there was always correlated structural defect. He thought the bearing of his remarks would be best appreciated by considering one conventional variety of indigestion, the so-called "nervous dyspepsia," about which there was such divergence of teaching in standard text-books. Under Dr. Allchin's scheme nervous dyspepsia would be defined as that form of disturbed digestion due to impaired innervation of either mouth, stomach, intestines, or associated glands, leading to imperfect changes in any or all of the different food constituents. The disordered nervous control might be due to: (*a*) disturbances of central origin, such as emotional states, anxiety, hysteria, neurasthenia, &c., or gross structural lesions such as cerebral tumour, meningitis, locomotor ataxy, &c.; (*b*) disturbances of reflex origin, as from the kidneys or ovaries; and (*c*) peripheral irritation of the nerves of the alimentary canal. The term "nervous dyspepsia," therefore, would not denote a group of symptoms, but indigestion primarily of nervous origin. It would be expected that the symptoms would be such as are directly traceable to disturbed motility and secretion, and such actually is the case in the vomiting due to fright or anxiety, the obstinate eructations of the hysteric, the vomiting from cerebral tumour or in the crises of locomotor ataxy, and in increased rectal peristalsis from fright. Flatulence is not a marked symptom and is a secondary result of the improper digestion of amylaceous constituents. The remote nervous symptoms, such as headache, vertigo, drowsiness, &c., were due to the formation and absorption of toxic substances. Dr. Allchin admitted that even by grouping symptoms the ascertainment of the cause was a matter of extreme difficulty, but he felt convinced that before any rational treatment could be propounded with any view of success these difficulties must be overcome.—Dr. MAGUIRE thought that it was instructive and of practical value to consider the subject from an embryological standpoint. It was recognised in neurology that the function latest developed was the first to disappear under conditions of strain and the first to reappear when health was re-established. In the embryo the first food was the albumin in the yelk sac, which required no digestion. After birth the child took milk, the proteid constituent, casein only requiring digestion, as the lactose and finely emulsified fat were readily absorbed. It was not till the age of six months that carbohydrates were digested, and power to digest fat in the mass was not developed till much later. In dyspepsia fat digestion, the last acquired, became impaired first, then carbohydrate digestion became disordered, but the power of digesting proteid in some form persisted. In cases of fat and carbohydrate dyspepsia great benefit was often obtained by putting patients for a time on an exclusively lean meat diet. Afterwards carbohydrate digestion might be aided by giving some active preparation of diastase, and he thought that acids such as lemon

Digitized by Google

juice aided the digestion of fat.—Dr. ALLCHIN, in reply, thought that more evidence was required in support of Dr. Maguire's very taking theories. He was not convinced that distaste for fat was lost before inability to digest starchy food showed itself. In some cases he thought that impairment of digestion of proteids occurred first.

OBSTETRICAL SOCIETY OF LONDON.

Puerperal Septicæmia treated by Anti-streptococcic Serum.—Early Ectopic Gestation complicated by Fibro-myoma of the Uterus.

A MEETING of this society was held on Oct. 5th, the President, Dr. C. J. CULLINGWORTH, being in the chair.

Dr. J. WALTERS and Mr. A. R. WALTERS communicated a paper on a case of Puerperal Septicæmia treated by Anti-streptococcic Serum. The patient, a multipara, aged thirty-four years, gave birth to a child in April, 1895. She again became pregnant in March, 1897. Severe flooding set in in May, followed by irregular hæmorrhages and foul discharge which lasted till April, 1897. The uterus was dilated and freely curetted on May 9th with strict antiseptic precautions and it was afterwards swabbed with carbolic lotion and with iodine liniment. On the 10th the patient was comfortable and the temperature was normal. During the next five days there was slight fever and the remains of a macerated fœtus were passed. On the 16th the patient had intense headache and an urticarial rash, and the discharge was more offensive. The temperature varied from 98·5° to 102·5°F., and the pulse was 100. The uterus was washed out with perchloride of mercury (1 in 2000). At 10.30 P.M. the patient had a severe rigor and the temperature rose to 104·5° and the pulse to 120. On the 17th the tongue was dry, the temperature ranged from 101° to 103°, and the pulse was 120; 10 c.c. of anti-streptococcic serum were injected. At 8.30 P.M. the patient was bright and cheerful and the skin was moist. The temperature was 98° and the pulse was 80. On the 18th the headache returned and the temperature rose to 100·5° and the pulse to 100. A second injection of 10 c.c. of serum was given and the temperature fell to 98° and the pulse to 75. The second injection was followed by very great depression which lasted for several days; there was also transient albuminuria. The patient recovered and there seemed no reasonable doubt that the recovery was entirely attributable to the use of the serum.—Dr. AMAND ROUTH said that it was difficult to be sure in any given case when several methods had been adopted that the successful ending was due to one of the methods only. Out of five or six cases treated by himself one had recovered from the septicæmia as a result of the anti-streptococcic serum alone. It was not wise to inject so potent an agent unless it had been previously ascertained that the infection was due to streptococci, and the ordinary treatment, especially removal of all débris, should not be omitted.—Dr. EDEN also thought it very important to ascertain the nature of the infection before using the serum. In Dr. Haultain's series a different form of infection was present in each case; in one the Löffler bacillus was present and the case was successfully treated by the diphtheria antitoxin.—Dr. G. H. D. ROBINSON agreed that it would be interesting to ascertain what microbe was producing the disease; but he feared that this would be practically impossible. He had investigated a number of cases bacteriologically but the results had been unreliable. Out of 7 cases which he had treated with the serum 5 of the patients had died, the treatment apparently having had no effect. 2 of the patients recovered; in one of these the only effect was that the patient seemed to sleep better afterwards; in the other patient, who had on the eleventh day a temperature of 104° and a pulse of 120 and membranous vaginitis, the injections of the serum were followed at once by a fall of temperature and the patient rapidly convalesced.—Dr. MCCANN said it was probable that more than one microbe was the cause of puerperal septicæmia. He suggested that the serum should also be used as a preventive in cases where sepsis would be likely to follow.—The PRESIDENT said that he did not quite agree with the opinion which had been expressed that the serum ought not to be administered until it had been definitely ascertained that the offending microbe in the cases under observation was the streptococcus. He thought, as streptococci were usually present, the serum ought to be given without waiting for bacteriological investigation. The safe rule of practice was to explore the uterus digitally with the finger under an anæsthetic (decomposing débris should be removed by the finger and reliance must not be placed upon the douche) and then to administer the serum without delay.—Dr. JOHN PHILLIPS had administered anti-streptococcic serum in several cases, but in only one was he certain that the patient's recovery could be attributed to its use. The patient had been for many weeks suffering from acute septicæmia. Curettage had failed to produce benefit. Twenty injections were given in the course of twelve weeks. The temperature, which was very high, was always lowered, the delirium ceased, and the skin acted, the effect lasting several hours. In this case repeated examinations of the discharges for streptococci gave a negative result.—Dr. TATE had seen several cases treated by the serum and in some of them the results appeared to be good. In one case the first injections were followed by improvement, but afterwards failed to give relief; possibly this case was one of mixed infection.—Dr. J. WALTERS replied.

The PRESIDENT read a paper on a case of Early Ectopic Gestation (? tubo-uterine) complicated by Fibro-myoma of the Uterus. The patient, aged thirty-three years, was admitted into St. Thomas's Hospital on Sept. 4th, 1897, said to be suffering from retroversion of the gravid uterus. Attempts had been made to reduce the supposed displacement but without success. The patient had had one child nineteen years before and had last menstruated during the last week of April, 1897. Five weeks later she fell down some steps and had pain in the back and in the abdomen. This passed off, but returned three weeks later and continued gradually increasing in severity. A fortnight before admission clots were passed and since then there had been an offensive discharge and for the last five weeks sickness every evening. Further attempts were made to reduce the supposed displacement. On Oct. 5th the patient was examined under ether and the diagnosis was made that the uterus was enlarged by fibroids and that there was also a pelvic hæmatocele due to an arrested tubal gestation. On the 21st an operation was performed and the fibroid uterus and gestation sac were removed. After careful examination of the parts removed it was concluded that the gestation was originally tubo-uterine and that the fœtus had been extruded either into a diverticulum of the tube (which was more probable) or into the abdominal cavity.—Mr. ALBAN DORAN observed that in pure tubal pregnancy the fœtus and placenta have been found to be in separate dilatations (Chaput's case). Hence in Dr. Cullingworth's case the fœtus possibly lay in a true diverticulum of the tube. Rupture had occurred early, but the membranes had partly protruded to stop up the leak and the fœtus had slipped into the protruding part, the placenta remaining behind.—Dr. AMAND ROUTH thought that Mr. Doran's explanation was probably correct.—Dr. ARTHUR GILES referred to a case which he had published in the Transactions of the society last year which also simulated retroversion of the gravid uterus.—The PRESIDENT, in his reply, said that this was the first case which had occurred in his practice in which a tubal pregnancy had involved the intra-mural portion of the tube.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—The inaugural meeting of this society for the session 1898–99 was held on Oct. 6th, Mr. T. D. Pryce, President, being in the chair. An address was delivered by Mr. William H. Bennett, surgeon to St. George's Hospital, on Varix, its Causes and Treatment, with especial reference to Thrombosis, which appears in full at p. 973. The President, at the conclusion of the address, called on Mr. Anderson to propose a vote of thanks to Mr. Bennett for his admirable address, and this was seconded by Dr. Handford and carried with much enthusiasm.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—This society held the first meeting of its seventeenth session on Oct. 7th at the West London Hospital. The President, Dr. S. D. Clippingdale, delivered the inaugural presidential address, choosing for his subject Some Consideration of the Life and Work of a General Practitioner. This address will be published in a future issue. A vote of thanks to the President for his address, proposed by Mr. F. Lawrence and seconded by Dr. H. P. Potter, was carried by acclamation.

Reviews and Notices of Books.

Outlines of Practical Surgery. By WALTER G. SPENCER, M.B., M.S. Lond., F.R.C.S. Eng., surgeon to the Westminster Hospital. London: Baillière, Tindall, and Cox. 1898. Demy 8vo. Pp. x. and 694. Price 12*s.* 6*d.* net.

NUMEROUS are the blessings which flow from the recent great progress of the medical sciences, but these beneficial results are accompanied by one disadvantage, and that is a great increase in the size of the modern treatises dealing with any one of these sciences. Pathology has made enormous strides during the last few decades, and its youngest and most important offspring, bacteriology, has only recently come into existence. Facts have accumulated to such an extent and so many theories have been evoked to explain them that it is not possible to include within a volume of reasonable size all the facts and all the theories with which the examiners expect a student to be acquainted. The difficulty of dealing satisfactorily with pathology in a treatise on surgery has induced the author of the volume before us to exclude from its pages the details of pathology and bacteriology; for these he refers the student to special treatises on these subjects, while he treats in this book only of those portions of surgery which are distinctly practical in nature. We must confess that there is much to be said in favour of this view, and a perusal of Mr. Spencer's volume goes far to make us agree with him on this point. Of course there are obvious advantages in having in one book all the pathology as well as all the surgery which the student will require, but if both subjects are to be treated thoroughly the bulk of the volume will militate greatly against its value. It is also true that the writing of a book limited to practical surgery is not without great difficulties. In mentioning the etiology of any morbid condition it is impossible to avoid reference to its pathology, and the same remark applies equally to the treatment, and therefore a writer would have to make a careful distinction between those facts of pathology which must be brought forward and those which may safely be left in special pathological treatises. This difficult task has been excellently performed by Mr. Spencer, and we have in several parts of the volume noticed with admiration the skilful descriptions with which we have met. To sum up the whole work we may say that it gives a good general account of modern surgery from the practical point of view; no space is wasted by descriptions of discarded methods of procedure, but the surgical treatment of the present day is presented to the student. Occasionally, perhaps, we cannot help thinking that the descriptions of some of the operations might have been fuller, though it is difficult to put a finger on any individual passage.

Before proceeding to a more detailed discussion of some of the points noticed during the reading of the book we should mention the illustrations. These are numerous, more than 100 in number, and they are, we should imagine, all original. They are in white on a black background and are certainly striking; in some instances the method brings out small points which would not be so clearly visible in an ordinary engraving and in all the object of the illustration can be readily seen. It may perhaps be considered captious criticism to say that the general effect is not always artistically pleasing, but this is not of great importance so long as the illustration conveys its meaning to the reader.

On page 3 we are told that gangrene of fingers has been caused by the use of even a weak solution of carbolic acid, owing to the power possessed by this drug of contracting the superficial blood-vessels. Of course it depends somewhat on what is meant by a "weak" solution of carbolic acid, but the statement surely is liable to give a wrong idea of the danger arising from the use of this antiseptic. In an account of the knots employed in surgery the author calls the reef knot the "simple knot," by no means a good name for it, and the "surgeon's knot" described does not need the third loop mentioned, for it adds nothing to its security or strength. It might well have been pointed out in the section devoted to sutures that suppuration along a suture is in general attributable either to the suture not having been completely sterilised or to the skin through which it was passed having contained pyogenic micro-organisms. We must protest against the spelling "leukocyte" which is employed throughout the work; there can be no justification for transliterating in the same word one *kappa* by a *k* and another by a *c*.

The section on General Anæsthesia is very good indeed. It would have been well, however, if the proportions of the ingredients in the A.C.E. mixture had been given. In the description of the methods of inducing local anæsthesia no mention is made of freezing with subsequent injection of a solution of cocaine; this is by far the most convenient method and has been employed even for abdominal sections.

In the account of "wound diphtheria" Mr. Spencer relates an interesting case which we do not remember to have seen before: "A house surgeon was doing a circumcision when his nose began to bleed and a drop of blood fell on the wound. The next day the child had a thick membrane covering the wound, and the house surgeon was ill with a severe attack of naso-pharyngeal diphtheria." It would be of interest to know if the diphtheria bacillus was found in the membrane which formed on the wound. With reference to infectious new growths it is not long ago that text-books on surgery laid it down as a rule almost without exception that carcinomata always affected the lymphatic glands and that sarcomata did not. Mr. Spencer expresses very clearly the general present opinion when he says that the milder forms of both carcinomata and sarcomata do not involve the lymphatic glands, but that in the severer cases of both forms of growth the lymphatic glands are nearly always affected. The author, in describing the lymphatics of the breast, mentions that it is rare for the glands of the anterior mediastinum to be involved in the early stages, and he appears to attribute it to there being only a few lymphatic vessels running with the perforating intercostal arteries, but the most probable reason of the rarity of the early involvement of the mediastinal glands is that nearly all carcinomata of the breast appear primarily in the outer segment of the organ and the lymphatic vessels from this part all drain into the axillary glands. A useful account is given of the treatment of retention of milk by "expression." This method is much too little known, for it is of great value and its employment would probably prevent many abscesses of the breast. The author, though advocating incision of a new growth of the breast before excision, does not explain that this is especially of value in diagnosing scirrhus from chronic abscess; a student is much more likely to remember and follow a rule of practice if he is told the reason for it.

The following sentence appears on page 334: "It is evident that since operations for the cure of hernia have come into practice the number of strangulation cases, and therefore the mortality from hernia, has been much diminished." We are not aware of any statistics which support this statement though it is by no means improbable. We should be interested to learn on what it is founded.

Is it not somewhat overstating the case to say that "an artificial anus in the small intestine is more hopeless than immediate suture"? The danger from an artificial anus in the small intestine depends entirely on its position in the bowel; if it is high up in the jejunum the wasting is great and death is almost inevitable, but low down in the ileum the

Digitized by Google

patient may be hardly the worse for it. Occasionally the phraseology employed is a little unhappy and the following may be quoted as a specimen: "The general causation of stone in the kidney is attributed to the uric acid diathesis, or to the water in districts where stone in the bladder is common."

It is surely a mistake to omit from the complications of gonorrhœa the most important of all—namely, gonorrhœal conjunctivitis. Though the surgery of the eye is not included in the compass of the volume, yet this severe complication should at least have been mentioned.

In quoting a few instances where we have not been quite able to agree with the views expressed by the author we have not intended to detract in the least from what we have said above as to the general value of the book. It would be best read, we think, in addition to, rather than in place of, other works, and its perusal should prove of benefit to every student of surgery.

Text-Book of Histology, including the Microscopic Technic. By Dr. PHILIP STÖHR, Professor of Anatomy at Würzburg. Second American from seventh German edition. Translated by Dr. EMMA L. BILLSTEIN, Director of the Laboratories of Histology and Embryology, Women's Medical College of Pennsylvania. Edited with additions by Dr. ALFRED SCHAPER, Demonstrator of Histology, Harvard Medical School, Boston. With 292 Illustrations. London: J. and A. Churchill. 1898. Pp. 424. Price 14*s*.

Dr. STÖHR'S treatise is one of the recognised text-books on histology for the German medical student. We learn from the preface that it has been translated into Italian, French, and Russian, and those who speak English are indebted to Dr. Billstein for having made a very readable translation, and to Dr. Schaper for adding considerably to the value of the work by the introduction of a chapter on the Placenta, and for sundry other improvements. It cannot, of course, be compared with Kölliker's monumental treatise, which, moreover, is not yet completed, but rather with that of Professor Schäfer recently published in this country and with those of Piersol, Satterthwaite and Miller in America. The description of the several tissues is clear but rather short, so that several points are omitted in each section. In that of muscle, for example, nothing is said of the disposition of the capillaries or of the intimate structure of Krause's membrane—in fact, the practice is adopted, which is commendable in a work intended for the guidance and instruction of a beginner, of stating only that which has been satisfactorily established, all controversial points being omitted. The general plan of the work is that it is divided into two parts, with several chapters in each. The first part is devoted to general technique, including the selection of a microscope, the preparation of microscopic specimens according to whether it is required to examine them in the fresh state or to harden or decalcify them, with a description of the various modes of sectioning, staining, injecting, mounting, and preserving them. The second part is occupied with the microscopic anatomy of cells and tissues, including epithelial, connective, muscular, and nervous tissues, which is followed by what constitutes the bulk of the work—the microscopic anatomy of the organs, as the brain, lungs, kidneys, and organs of sense. Finally, there is an appendix giving the details of microtome methods. The brevity of the descriptions is in part compensated for by the number and excellence, as well as the originality, of the illustrations and for the additional remarks that are given under the head of Technic. The "technic" describes the best mode of dealing with each organ to enable the beginner to obtain sections, to prepare them for mounting, and to preserve them.

We give an extract which will show the manner in which the "technic" is treated. It deals with the gastric mucous membrane and is written with the object of instructing the student in the method of demonstrating the "chief" and "parietal" cells of the fundus glands. The mucous membrane is directed to be cut vertically and horizontally and the sections to be stained with Hansen's hæmatoxylin. Then they are to be "thoroughly washed in 30 c.c. of distilled water which must be changed as often as it becomes bluish—about once or twice. Transfer them to 5 c.c. of a $\frac{1}{10}$ per cent. solution of Congo red for from three to six minutes, wash two minutes in distilled water, and mount in dammar. If the sections are too thick everything appears red; the large red parietal cells cover the smaller chief cells. Examine the thinnest parts of the sections, especially the fundi of the glands, where the parietal cells are not so exceedingly profuse. The parietal cells can be recognised with the low power as isolated red spots on a rose-red ground. With the high power the pale-blue smaller chief cells can be seen. The very narrow lumen of the fundus glands may be best seen in cross sections (sections parallel to the surface of the mucosa). The lateral twigs of the chief lumen can only be perceived in very favourable sections." References are made to another section for the preparation of Congo red and there is a reference to one of the woodcuts. The general get-up of the book reflects great credit on the publishers, for the illustrations are so delicate as to require very smooth paper and careful printing to obtain good impressions.

Aphasia and other Speech Defects. By H. CHARLTON BASTIAN, M.A., M.D. Lond., F.R.S. London: H. K. Lewis. 1898. Pp. 366. Price 15*s*.

THE basis of this most important work is the Lumleian Lectures delivered before the Royal College of Physicians last year and published at length in our columns at the time.[1] These lectures are supplemented by the consideration of fresh problems and the addition of numerous cases elucidating or illustrating many points of the subject, and in its present form Dr. Bastian's treatise must be regarded as one of the most complete and perhaps the most philosophical of all our treatises on speech and its anatomical, physiological, psychological, and practical relations. After an introduction which deals in a very interesting manner with the relations existing between thought and language, the different forms of speech defect are considered, and in the succeeding chapters the various structural and functional disorders correlated with them. Modes of recovery from aphasia are then discussed and such interesting problems as are afforded by the state of the musical faculty, amimia, mirror-writing, &c. In conclusion the etiology of speech defects, their diagnosis, prognosis and treatment, and their relation to capacity for exercising civil rights are exhaustively dealt with.

Such a brief examination of the contents of this book will be sufficient to indicate its scope. The views on speech problems with which Dr. Bastian's name is so inseparably connected have been discussed in our columns on more than one occasion, and while in this volume no material modification of these views has been made, fresh confirmatory evidence of their reasonableness is abundantly furnished. Dr. Bastian's view is that the so-called motor areas in the brain are really sensory centres "of kinæsthetic type," and in connection with speech processes he believes there are two centres of this type—a glosso-kinæsthetic centre related to articulatory processes and a cheiro-kinæsthetic centre in connexion with writing processes. Besides these there are an auditory word centre and a visual word centre—sensory centres—and lesions accounting for speech defects

[1] THE LANCET, April 3rd, 10th, and 24th, and May 1st, 1897.

Digitized by Google

are to be looked for in those centres or in the fibres connecting them with each other or with the motor centres in the bulb, or in these motor centres themselves. Such a scheme leaves no necessity for the "propositionising centre" formulated by Broadbent and those who think with him, and on this Dr. Bastian firmly insists. This is not the place to discuss the *pros* and *cons* of the two theories. Suffice it to say that in the work before us the author's view is clearly enunciated and is supported by a coherent, closely reasoned argument which will no doubt carry conviction to many. But besides this main theme the numerous and interesting subsidiary problems are most clearly discussed and elucidated, and we congratulate the author on this the crowning edifice of his brilliant and philosophical labours on the subject of speech.

On Maternal Syphilis, including the Presence and Recognition of Syphilitic Pelvic Disease in Women. By JOHN A. SHAW-MACKENZIE, M.D. Lond. London: J. and A. Churchill. 1898. 8vo, pp. 223. Price 8*s.* 6*d.*

THE etiology of the numerous forms of pelvic inflammation to which women are liable was for many years very obscure, but it was gradually proved that in many cases the inflammation was due to the extension locally of a gonorrhœal vaginitis or endometritis; in many other cases the condition results from some form of septic infection occurring especially in connexion with parturition; but it cannot be said that these two causes will account satisfactorily for all the cases of pelvic disease. The author of this volume is of opinion that in no small proportion of the cases pelvic inflammation is syphilitic in origin. Frequently no history can be obtained of any primary sore, but it is not always easy to find a chancre in women even when it is present, and therefore it is not surprising that no account can be obtained of the presence of such a lesion when several years have elapsed since the time when it probably appeared. In some cases, as Dr. Shaw-Mackenzie shows, undoubted secondary signs may follow a vaginal discharge which was considered to be gonorrhœal in origin. In other cases, again, the author thinks that the syphilis may not have been acquired, but was hereditary in origin. The results of treatment certainly support in many instances the contention that pelvic troubles are due to syphilis. All who see much of syphilis must have met with numerous cases in which lesions certainly syphilitic occur and yet no trace of any syphilitic history is obtainable. Dr. Shaw-Mackenzie is also of opinion that through a mother suffering from inherited syphilis the disease may be transmitted to a third generation. It is very difficult to prove this proposition, but he adduces many cases which certainly afford it some support. In the treatment of the obscure cases of syphilis with which this work deals the author attaches most value to fumigation and inunction.

The whole subject is difficult, but we think that Dr. Shaw-Mackenzie has done much by the publication of this work to clear up some of the difficulties which it presents.

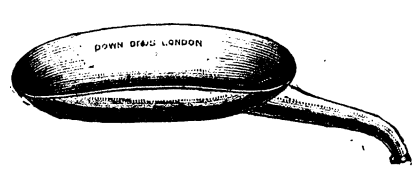
Text-book of Zoology. By H. G. WILLS, B.Sc. Lond., and A. M. DAVIES, B.Sc. Lond. London: W. B. Clive. 1898. Pp. 366. Price 6*s.* 6*d.*

THIS work is the first of a series, to be soon followed by a text-book of Botany, intended to minister to the wants of students preparing for the intermediate science and preliminary scientific examination of the University of London and other similar tests. The method adopted by the authors is that of the selection of certain types beginning with the rabbit, to which more than a third of the book is devoted, which are carefully worked out. The other types of the vertebrata selected are the frog, dogfish, and lancelet, and of the invertebrata the paramœcium, polype, earthworm, anodonta, and crayfish, which are given in less detail. There is a very good chapter on Development. The book is not intended, and should not be used, as a mere cram-book, but the student should read it with the specimens before him; if this be diligently practised, he will obtain a good idea of some of the principal groups of the animal kingdom. Questions which have been asked, or are likely to be asked, are appended to each chapter, and we must add a word of praise for the many clear and excellent woodcuts illustrating the text, the drawings for which have been prepared by Mrs. Davies.

New Inventions.

NEW URETHRAL SYRINGE.

AT my suggestion Messrs. Arnold and Sons, London, have made a urethral syringe which is a modification of one made by them for me and described in THE LANCET of Oct. 17th, 1896. To repeat, the syringe consists of a reservoir to hold 2 oz. with a pipe 5½ in. in length, size No. 8 or 9 catheter. The previous syringe had the pipe channelled on the exterior to allow of the free return of the injection; I find this channelling can be dispensed with if my instructions for using the syringe are carefully carried out, which are as follows. The syringe being filled in the usual manner the pipe is to be dipped in carbolic oil; now, gently insinuating the nozzle into the meatus by a rotatory motion, the pipe is made to glide slowly in to its full length. No pressure is to be made on the penis, which is allowed to lie in the hand. The reservoir is to be slowly compressed and the injection will be found to return back by the side of the pipe. To the many advantages which I claimed for the syringe in the treatment of gonorrhœa over other syringes I may add another—viz., that the passage of a pipe 5½ in. in length and stated diameter tends to prevent the possibility of stricture in the spongy portion. This syringe will be found much cheaper in price than my previous instrument and less formidable to a nervous patient. I have prescribed this form of syringe for the last ten years in the treatment of gonorrhœa and my having found it most efficacious is my reason for bringing it under the notice of the profession.



RALPH STONEY, L.R.C.S. Irel., &c.

Gloucester-terrace, S.W.

NEW DRESSING TRAY.

THE accompanying illustration represents a useful kidney-shaped tray for receiving the washings during uterine or vaginal douching and conveying it through rubber tubing to a pail beside the bed or operating table. The spout forms the handle which is curved so as to allow it to be easily held

in one hand close to the buttocks without bringing the patient over the edge of the bed. By using this tray, which can be carried in the obstetrical bag, the operator can avoid soiling his hands or the bed. It will also be found useful in syringing ears or douching wounds. It is manufactured by Messrs. Down Brothers, of St. Thomas's-street, London, S.E.

THE LANCET.

LONDON: SATURDAY, OCTOBER 15, 1898.

THE city of Liverpool kept Saturday last, Oct. 8th, as a gala day, the occasion being the opening of the new THOMPSON-YATES Laboratories of Physiology and Pathology by Lord LISTER and the conferring upon him at the same time of the degree of Doctor of Science of the Victoria University. We give in another column a report of the proceedings, but no mere account of what happened, of speeches which were delivered, or of addresses which were read, conveys any idea of the enthusiasm of the people of Liverpool over these two events. The city identified itself with each function in the closest manner. Within the walls of St. George's Hall crowds watched the ceremony which added to the long list of scientific titles enjoyed by the President of the Royal Society the title of Doctor of Science of the Victoria University; without the hall crowds lined the streets, taking the greatest possible interest in the arrival and departure of the distinguished guests of the University College of Liverpool—guests many of whose names are a synonym for learning all over the world; in the Town Hall the Lord Mayor entertained those who had assembled in honour of the occasion with the heartiest of civic welcomes; and every house where the numerous visitors were billeted was the scene of luncheons, dinners, and friendly receptions. What does all this connote? It is certain that if any university, from the most ancient to the most modern of the seats of learning in the kingdom, had five-and-twenty years ago out of its own resources or out of private munificence made some addition to its teaching facilities not a small fraction of the cordial excitement which prevailed last week in Liverpool would have been aroused. A few persons professionally interested in education would have attended the ceremony; a few citizens, struggling against the feeling that the donor might have made a more practical use of his wealth, would also have been present; and the enthusiasm of the community would have been level with that aroused by, say, the election of an alderman or the gift to the populace of a new drinking-fountain.

Only two weeks ago we referred in a leading article to the tendency towards a fusion of interests between the university and the city in which it is placed as forming one of the most significant as well as one of the most recent developments of modern education, and now we have in Liverpool a remarkable illustration of this spirit of sympathy. University College, Liverpool, has received from Liverpool the sum of £400,000 or thereabouts during its comparatively short life. This great sum has been given ungrudgingly and established at once a bond beween the College and the city, but the sentiments of gratitude on the one hand and of satisfied generosity on the other will not account for all the mutual goodwill expressed at Liverpool. The princely present of the Reverend SAMUEL ASHTON THOMPSON-YATES to the College of furnished and equipped laboratories for the study of physiology and pathology cost him no less than £28,000, and Liverpool, or, rather, all England, may well be proud of this open-handed citizen, as the University College has a right to be proud of such a signal and munificent mark of confidence in its work and belief in its future. But the words of Mr. R. B. HALDANE, M.P., and Professor MICHAEL FOSTER at the Town-hall in the evening, no less than the appreciation with which those words were received, show that wider sentiments even than these have been at work in Liverpool to evoke the universal enthusiasm manifested. It is clear that to all gathered together for the inauguration ceremony of the THOMPSON-YATES Laboratories the real significance of the occasion was that another and a great step forward in national education and national progress was being taken, that another practical proof was being furnished of a new educational spirit. One more nail—nay, many and strong nails were being driven into the coffin of the old-fashioned university education which inculcated a spirit of aloofness into its disciples, which led to a division of interests between the best workers and the highest thinkers, and which deprived practical men of the counsels of the learned, while it shunted the learned into careers of compulsory sterility. Medical men will experience a feeling of profound gratification at any successful blow which is dealt at such a system, for it is in the modern curriculum of the medical student that all the good in the old theories of education is most closely combined with all the good in the new. Let us not be found laughing at the belief cherished by our grandfathers and probably by our fathers that the real man of culture was the man who could write correct Greek verse. The reason for this error is obvious. One of our greatest schoolmasters and most original thinkers, EDWARD THRING, in an essay defending the study of the dead languages, says roundly that no sane person holds himself a poet because he writes good Iambics. But THRING immediately proceeds to show in his own convincing way that the study of Latin and Greek forms the finest mental exercise known to him and the most convenient medium for inculcating into lads the virtues of industry and accuracy. He acknowledges that but few of the many who read classical literature ever arrive at any real comprehension of its supreme excellence; but, while revering this literature himself as consisting of consummate masterpieces of artistic skill and beauty of form, he treats the study of it simply as means to the end and not as the end itself. This is what the older university men were, so many of them, unable to do, and as a consequence that most stupid article, the man who thought that a first-class university degree would stamp him as a first-class man for the rest of his life, was produced by them in considerable quantities. The real ability of such men was lost to the nation, while in places where learned guidance would have been most valuable the guides were wanting.

Now the modern education of the medical man forms a close link between the old and the new theories of education. It is an education which is living and progressive, which in its higher degrees produces men of indisputable learning and culture, and which is none the less utilitarian. The

Digitized by Google

most tangled passage of a corrupt Greek author requires no more absolute care for its right rendering than a physiological experiment asks from the student. No study in the world demands greater accuracy than anatomy. The worker in the vast fields, explored and to be explored, of bacteriology must add to care and accuracy both inventiveness and resource. These qualities when displayed in the acquirement of a classical education were too often wont to lead to practical failure in life, though perhaps associated with distinct academic success, because the student was allowed to believe that his attainments constituted in themselves an equipment to face the world. But the highly trained scientific man grows in use to his community as he grafts on to the lessons of his education the experiences of his work, and this, which is true of all scientific men, is true of none more strictly than of medical men. These are the facts which explain the popular enthusiasm excited by the recent ceremonies in Liverpool. The effusive approval manifested by the citizens of the direction of Mr. THOMPSON-YATES'S generosity may be taken as a proof that the inhabitants of Liverpool see growing up in their midst an institution which will furnish them with leaders of thought and leaders of work, who will conduct them to commercial successes and sanitary well-being instead of spending a lifetime in arid combats with aorists.

WE cannot in the public interest forbear to call attention to the facts elicited at an inquest held on Oct. 8th by Mr. G. F. ROUMIEU on Major CECIL LESTER, an Instructor in Military Topography at the Royal Military College, Sandhurst, who died on Oct. 5th after being attended for a month by a lady "Christian Scientist." From the evidence given at the inquest it would appear that Major LESTER suffered from tuberculous peritonitis and that from August 19th to Sept. 5th he was under the care and treatment of Dr. CLARKE, Principal Medical Officer at the College, and his colleague, and they, recognising the gravity of the case, had called into consultation a physician from Reading and another from London. The condition of the patient gradually grew worse and the physicians felt it to be their duty to inform Major LESTER'S wife and father that he was in a most critical state, and that, although recovery was not absolutely hopeless, it could scarcely be expected. On Sept. 5th Dr. CLARKE was informed that a Christian Scientist had been sent for and that further medical attendance would not be required. Mrs. GRANT, a widow lady, stated to the jury that she received a telegram asking her to attend Major LESTER to give "Christian Science Treatment," and that she commenced her treatment at once before she saw the patient. In reply to the Coroner she said that she treated the patient "by what we should call taking up the right thought of the omnipotence and love of GOD." She stated that she had never had any experience in the management of peritonitis. No drugs of any kind were administered by her, nor did she give any material remedy whatever to alleviate the pain; yet she believed her treatment had the desired effect. General LESTER, in his evidence, said that there was a marked improvement in his son's condition after the treatment of Mrs. GRANT commenced, but he did not know whether that was merely a coincidence.

On Oct. 5th Major LESTER died and Dr. CLARKE, not having seen the patient for a month, rightly and properly refused to give a medical certificate of the death. A post-mortem examination testified to the accuracy of the medical diagnosis and the jury found that the deceased died from tuberculous peritonitis. They added the following riders to their verdict: "1. The jury express their entire satisfaction with the treatment and action of Dr. CLARKE and Dr. GILLESPIE throughout the entire case. 2. The jury also desire to express their sense of abhorrence at the so-called treatment of the deceased by Mrs. GRANT as representing the Christian Scientist Society in not using material means for the alleviation of his suffering." Dr. CLARKE'S high repute and the close attention which he gives to his cases in the office which he has so long and so honourably held are in themselves a guarantee that no consideration or kindly thought was likely to be overlooked in the efforts made on behalf of his suffering brother officer. Fortunately the case is not one where the skill or the treatment of the medical advisers was at any time in question. They themselves recognised the fact that, humanly speaking, recovery was well-nigh hopeless and scarcely to be expected and they said so honestly to the anxious relatives. It is not for us to say that at this stage of apparently hopeless despair it was unnatural in the relatives to wonder if there was anything more that they themselves could do; nor as a mere matter of sentiment dare we blame them for cherishing at a sorrowful crisis what General LESTER described to the jury as a rational and reasonable hope" that there might be something in the "Christian Science" treatment which would lead to recovery. But the contemplation of his death-bed leads us to pass briefly in review the reasons given by the exponent of the Christian Science Treatment for the hope that is in Christian Science Treatment —an excellent and taking phrase but surely a misnomer from beginning to end. Mrs. GRANT told the jury that she gave no material remedy to alleviate the pain. Where was the treatment? Mrs. GRANT told the jury that she had no experience in the treatment of peritonitis; yet she commenced her treatment directly she got the telegram and before she had seen the patient. Where was the science? Mrs. GRANT, "taking up the right thought of the omnipotence and love of GOD," told the jury that she did not believe that suffering was sent by GOD, and she contended that JESUS CHRIST never sent the sick to physicians. If the agony at Calvary for man's redemption was a GOD-sent reality, and if the Miraculous Healer told the Pharisees that "they that be whole need not a physician, but they that are sick," where is the Christianity of the Christian Scientist?

Though sufficiently vital to demand notice we have no desire here to labour this aspect of the question. We fee it rather to be our duty, our solemn duty, to warn Christian Scientists of the grave responsibility which they incur in regard to the health and lives of their fellow-beings. We must point out that their methods of so-called treatment are ignorant devices, spurious in themselves and altogether unscientific and opposed

Digitized by Google

to common sense. The Christian Scientist talks as if his (merely human) activities were set in motion and pervaded by an atmosphere of Divine potentialities. In an almost flattering way he, as it were, "stands in" with GOD, or, as Coroner ROUMIEU bluntly put it at the inquest, he "tries to usurp the special power which CHRIST had." We feel it, further, to be our duty to point out that apart from evils which may result to individual members of the community from it, the Christian Science treatment is neither more nor less than a *fin de siècle* fad, a drawing-room cult, and that it is the counterpart of the culpable negligence which has brought the Peculiar People of the less educated classes within the range and operation of the criminal law of the country.

THE Public Health Committee of the Lond n County Council are, we are glad to see, properly impressed with the need of an active administration for reducing the risks to the London community from the milk of tuberculous cows. That this risk is in every sense a substantial one there is no manner of doubt. The subject has been fully inquired into by two Royal Commissions, whose recommendations only await the action of Parliament. If the London County Council adopt, as we anticipate that they will, the suggestions of their Public Health Committee, they will seek at once the necessary powers for dealing with this matter, and it is not probable that they will be refused by the Government.

The Public Health Committee have included in their recommendations to the Council the advice to deal with the inspection of the meat-supply of London also. Such inspection is obviously needed, not only on account of tuberculosis, but in respect of other and obvious conditions. The Committee have been for some time under an instruction from the Council to report as to the desirability of establishing public slaughter-houses throughout London and as to the facilities which such a system would afford for the better inspection of the meat-supply of the metropolis. In consequence of this instruction Mr. SHIRLEY MURPHY, the medical officer of the Council, has utilised such opportunities as his holidays have given him—a piece of public spirit, by the way, which cannot be too highly commended—in visiting certain cities in this country and on the continent and has thus made himself acquainted with the system adopted in each for insuring a wholesome meat supply to the inhabitants. The result of his visits to Edinburgh, Manchester, Liverpool, Berlin, Hamburg, and Copenhagen, among other great and important cities, was incorporated by him last summer in a report to the Public Health Committee, in which he showed the inadequacy of the inspection employed at present in the case of meat consumed in London, and pointed out that for the protection especially of the poorer inhabitants, who are the purchasers of the meat which is most likely to be tainted, it was necessary that a system of examination of all dead meat brought into the metropolis should be instituted, save in cases where the meat could be shown to have already undergone examination in a public slaughter-house. In order to insure the inspection of meat killed in London Mr. SHIRLEY MURPHY considered it absolutely necessary that all animals should be killed in public slaughter-houses, where alone an adequate and systematic inspection of the meat could be made. The Public Health Committee now report that they concur in Mr. SHIRLEY MURPHY'S views—views which, it should be remembered, and which the Public Health Committee remind the Council, have received quite recently very exact endorsement in the report of the Royal Commission on Tuberculosis. The Royal Commission on Tuberculosis held the use of public slaughter-houses in populous places to the exclusion of all private slaughter-houses to be a necessary preliminary to a uniform and equitable system of meat inspection, and recommended that powers should be conferred on local authorities to declare, as soon as a public slaughter-house was erected, that no other place should be used for slaughtering, a certain short space of time being allowed for the owners of private slaughter-houses to turn their property to some other purpose.

The resolution which the Public Health Committee invite the County Council to adopt is as follows and defines exactly what the Committee aim at: "That, in the opinion of the Council, it is desirable that as a first step towards insuring the proper inspection of meat private slaughter-houses should cease to exist in London and that butchers should in substitution be afforded such facilities as are necessary for the killing of animals in public slaughter-houses to be erected by the Council." We cannot doubt that the Council will adopt this resolution of their Public Health Committee, founded as it is upon the personal investigations of their medical officer and supported by the report of a very able and painstaking Royal Commission. It may be expected that in London, as elsewhere, opposition will be shown by butchers owning private slaughter-houses. But the record of the County Council is so good in matters concerning the public health, their actions have been so judicious and so open-eyed, that we look forward with confidence to their support of a much-needed sanitary reform in London. Questions of compensation may arise and some expense will have to be incurred in building new public slaughter-houses in convenient situations, but these are small matters compared to the getting rid of private slaughter-houses, which are the only obstacles to the introduction of an efficient system for preventing the sale in London of meat unfit for human food.

Annotations.

"Ne quid nimis."

THE VENTILATION OF UNDERGROUND ELECTRIC RAILWAYS.

THE substratum of the metropolis is being pierced in all directions radiating from the City for the construction of underground electric railways. The electric railway running from the north end of London Bridge to Stockwell has been in working order for some years now, and apparently without any serious hitch having happened in the arrangements. This is the more satisfactory because this line was the first in London, we believe, to apply electric motive power on an underground railway. Not very long ago another line was opened between the Mansion House and Waterloo which has already proved a great convenience to the public.

Digitized by Google

Other lines are in progress. So far the lines completed show the indisputable advantage of electric traction over steam traction, at least for underground railways. The passages are free from choking sulphurous smoke and the atmosphere is as satisfactory as could be expected under the circumstances. A recent occurrence on the Waterloo and City Electric Railway would, however, seem to show that while the pollution of the underground air by smoke is of course avoided no extra precautions have been made for securing the adequate ventilation of the tunnel in the event of emergency. It must not be forgotten that visible smoke and plainly discerned smells serve after all in the ordinary underground railway as an excellent index of the state of the air, but in the absence of these things, as on the underground electric railways there is no such guide, and insidious poisoning by repeatedly inspiring human exhalations is possible, if not, indeed, suffocation. To some extent these conditions were realised last week on the Waterloo and City line in consequence of the breakdown of a train. It appears that a train going Citywards was full to overflowing by reason of a crowd returning from viewing the Guards on their coming home from the Soudan. The motive power was unequal to the load and the train stopped. The delay was sufficiently long to cause a marked sense of suffocation to the passengers and a degree of panic, while it is reported also that the lights failed. It was fortunate that the stoppage occurred within a comparatively short distance of the City end, so that ultimately the passengers could escape by leaving the train and walking the rest of the distance. It is assumed, and correctly, that the advance of a train through a tube which it closely fits is sufficient to maintain an adequate change of air in the tunnels, in which case no extra provision for ventilation need be made, but in the event of a breakdown the supply of air would soon be exhausted and the result might be disastrous and comparable with the awful historic tragedy of the Black Hole in Calcutta. Either an improved system of keeping up a supply of air must be adopted on the underground electric railways or else a relay of motors must be immediately at hand at both ends of the tunnel to draw the trains out in the event of a breakdown. The former course would be safer, for in the event of a train leaving the rails the delay would be necessarily great and correspondingly serious to the imprisoned passengers. The matter must be referred to the Board of Trade, which we hope in the present instance has not committed a serious oversight. Steps must be taken, if such by some inconceivable want of perspicuity is not already the case, to remove the awful possibility of suffocating a train-load of people. It would be interesting to know whether the underground electric lines in course of construction have included in their plans the provision of an air-supply should any necessity arise.

THE BIRMINGHAM CLINICAL BOARD.

THE prizes awarded by the Birmingham Clinical Board for success in clinical studies in the Birmingham hospitals were distributed on Thursday, Oct. 6th, in the clinical lecture theatre of the General Hospital, by Sir William Mac Cormac, President of the Royal College of Surgeons of England, who delivered a brief address on the Scientific Progress of Surgery and the Importance of Accurate Clinical Observation. Sir William Mac Cormac told his audience that he had been trained at a provincial hospital and that it was therefore with the greatest pleasure that he came to Birmingham to award the prizes. Proficiency in clinical work Sir William Mac Cormac considered to be a most important part of all teaching in medical schools:—

"It was to obtain that proficiency in order to cure others that the student examined the framework of the human body and the functions of every part of it. It would be well if that knowledge were more extensively acquired, and he was sure that the better equipped by preliminary training in general knowledge and general culture in science they were when they came to their studies the better able would they be to secure the advantages which clinical studies presented. In order to obtain this proficiency they must, above all, develop and train that very precious quality—the faculty of observation. Many persons saw while they did not observe. In the wards and elsewhere they had opportunities of cultivating the faculty of observation and all the great physicians and surgeons of our time and of past times had possessed it in a large degree, and had cultivated it to the highest possible point. He need only refer to one who was recognised not only in this country but all over the world as one of the greatest of surgeons, the founder of scientific surgery. The record of his life showed what a profound and regular observer he was. Even in his boyhood he used to take his observations of the common things about him, of things that, perhaps, most of them would pass by unheeded, and probably he was a very unpleasant companion, for he often pestered people with questions about which nobody cared and probably nobody knew anything about. That quality of observation, when they had cultivated it, would lead them to see things which otherwise would be quite beyond their ken, to notice and appreciate facts which others would pass by. No doubt many students had been amazed at seeing a physician or a surgeon in a ward 'spot' at once some disease, or injury, or malformation which they themselves would not have noticed. It seemed to them a kind of instinct or intuition, but it came from a long habit of observation and the long experience which had cultivated that power. He could not too strongly commend to them the great advantage which it would be to cultivate this faculty."

Sir William Mac Cormac concluded by describing to his audience the new clinical laboratory of St. Thomas's Hospital.

URBAN BURIAL.

THE *North American Review* for August contains an article by Dr. Louis Windmüller entitled "Graveyards a Menace to Health," which has attracted considerable attention. It will probably be news to a large number of the readers of THE LANCET to learn that New York City is as plentifully supplied with graveyards situated in crowded parts of the town as almost any old English or continental town, but, according to Dr. Windmüller, in the early part of this century graves were in evidence in New York to such an extent that an Englishman who visited the United States speedily returned when he found every street in New York lined with headstones. In regard to the objection raised against cremation by members of the medical and legal professions on the assumption that poison cannot be detected in the ashes the writer of the article says that this view is now generally abandoned and considers that in suspicious cases intestines might be preserved before the rest of the corpse is consigned to the furnace, but that in any case fire would scarcely consume a mineral poison. Here the writer seems to us to under-rate the heat of the furnaces usually employed, under which many minerals would certainly be volatilised. Dr. Windmüller goes on to say that when mineral poison is found in the stomach of a disinterred body which has been embalmed it cannot be considered a conclusive proof of crime because the fluid injected into such bodies usually contains arsenic, but such a small percentage of bodies undergoing interment have been previously embalmed that the fact is hardly worth adducing as an argument. Dr. Windmüller next expresses anxiety as to the soil in the neighbourhood of great cities if the usual system of burial is persisted in. If 4000 corpses are crowded into the space of one acre, the limit in the case of the most populous graveyard, and if the present rate of mortality in New York—20 per 1000 inhabitants—be accepted as the standard, with a population of 3,500,000 New York

Digitized by Google

must provide room for 70,000 burials annually and would require annually 17½ acres to bury them in. Unless custom is changed the available room in the vicinity of large cities will, he thinks, gradually be absorbed by the remains of the dead. Dr. Windmüller then proceeds to review the earth burial from a sanitary standpoint and remarks: "Innumerable proofs furnished by scientific men of all ages, recently by Dr. Pasteur, show that earth retains instead of destroying the germs of disease contained in a body and that it in some degree will vitiate its surroundings." Among other points he cites in support of this contention one that the French Academy of Medicine located the origin of diseases of the lungs and throat in putrid emanations from the Parisian cemetery of "Père la Chaise," and, again, that drainage from cemeteries in Philadelphia has polluted water in Fairmount reservoir. The second of these points does not amount to much, for no one doubts that a cemetery can damage a water-supply. The article concludes with these words: "Since thirty years ago cremation has been reintroduced in civilised communities many thousand bodies have been thus disposed of, including those of Hans von Bulow, George du Maurier, Jacob Moleschott, F. Gregorovius, and Anton Seidl. Instead of condemning their memory because they refused to allow their corpses to become offensive, let us follow their noble example and help to remove one of the most odious stains on our civilisation." As a single-minded plea for cremation regardless of the arguments of controversialists on the other side Dr. Windmüller's paper is worth perusal.

THE RIGHTS OF EXPERT WITNESSES IN THE UNITED STATES.

SOME consternation has been caused in the profession of the United States by the decision of the Supreme Court in the case of J. N. Dixon *versus* the People of the State of Illinois, which was filed in 1897, and is the subject of a paper read recently to the Illinois State Medical Society and reported in the *Medical Record* of August 27th. In January, 1895, Dr. Dixon of Sangamon County, Illinois, in answer to a subpœna appeared in the Circuit Court as an expert witness. He was confronted with a hypothetical question relating to injuries, of which he had no personal knowledge, said to have been sustained by a woman whom he had never known. He was asked as to the probable results of a fall on a defective side-walk in producing certain injuries, and after receiving the assurance of the court that he was called as an expert witness only he respectfully declined to answer, basing his refusal on the ground that an expert witness is entitled to a different and greater compensation than an ordinary witness is allowed and that an expert is not required to give expert testimony without compensation as an expert unless a reasonable compensation shall have been paid and provided for. The court held his refusal to be contempt of court and fined him $25. An appeal was allowed to the Appellate Court. This court upheld the judgment of the Circuit Court, stating that the statute has fixed the compensation to be paid to all witnesses and "the law requires every person when duly subpœnaed to appear as a witness and accept as full compensation the statutory allowance, however inadequate it may be." The court took occasion to state that knowledge gained by study, observation, and experience is not "property" within the meaning of the word in the sense that "private property shall not be taken or damaged for public use without just compensation"—"the word property means tangible things and rights which accompany, or are incident to, the use, enjoyment, or disposition of such things." In June, 1896, the case came to the Supreme Court on a further appeal, when Dr. Dixon's attorney referred to the custom of the ancients and quoted the authorities and practices of every civilised country according to which expert testimony is either property or "particular service" entitled to full and just compensation. The court came to the same decision as the courts below and decided "that a physician when subpœnaed and interrogated as an expert witness may be compelled to testify without any pay other than the statutory fee. He must testify in civil as well as in criminal suits, since in either case the object is to promote public justice and ensure the peace and good order of society." Refusal to testify is contempt of court. Fortunately this is only the law of the State of Illinois, and we venture to hope it will not be adopted by other States. According to it the busiest and most skilful medical men may be subpœnaed by any party in any case and will be obliged for a miserable fee to leave proper and greater work without any adequate remuneration. What would lawyers say if an eminent master of their profession were summoned from his ordinary duties by subpœna and paid the fee of an ordinary witness?

A "QUESTIONABLE SHAPE"—A POPULAR ERROR.

UNDER the title of "In Dead Eyes" an evening contemporary recently made a statement which carries its own confutation with it. It is to the effect that a physician and enthusiastic photographer, being desirous of testing the amount of truth in the theory that dead eyes retain complete images, had carefully examined the eyes of hundreds of dead people, and though he had never seen anything like a distinct picture mirrored he had certainly distinctly traced both letters and objects on the *iris* of the eye, and that when the photographic test was applied these images became visible. In one case a capital letter of peculiar form was shown which could be traced to a Testament held in the hands shortly before death. In another case a numeral was distinctly pictured which was traced to a clock face in the room. The article in question continues: "The chief scientific paper of France only the other day gave full particulars of a case where a woman who died in one of the hospitals had two numbers, 10 and 45, mirrored in the *iris* of her eyes." These absurd stories originate in the well-known experiments of Kühne on the visual purple of the retina, in the course of which he showed that by making special arrangements the cross-bars of a window focussed on the *retina* could be brought into relief. The enthusiastic photographer, if he be not misquoted, ought to have known that no well-defined images of the external world are cast upon the iris and none, therefore, could be preserved. The surface of the iris is far too uneven to act as a mirror. Moreover, as no arrangement were made to prevent the further action of light after death they would if formed be certainly obliterated as the image on a photographic plate would be if permanently exposed. The only mode in which an image impressed on the retina could be rendered visible would be to adopt the method of Kühne—viz., by exposing the eye previously kept in the dark for a minute or two to an illuminated object, then extirpating it, opening it, and immediately plunging it into a solution of alum. The image develops in the course of twenty-four hours.

SYPHILITIC PHLEBITIS.

IN *La France Médicale* of August 12th Dr. Barbe very truly remarks that syphilitic phlebitis is not often described, perhaps because it is imperfectly known and passes unnoticed. Sometimes the lesion is localised (venous gumma), sometimes it affects a certain extent of the vein. Langenbeck was one of the first who drew attention to syphilis of the veins. In 1881 he extirpated a tumour in the neck as a cancer. The microscope and ulcerations in the mouth and throat which followed showed it to be a gumma. It grew from the external coat of the jugular vein. He relates

Digitized by Google

another case in which a similar diagnosis was made and a gumma of the femoral vein was removed. The patient died from pyæmia. In 1872 Gosselin observed in a syphilitic woman, aged sixty-five years, a painful and tender swelling in the upper part of the calf beneath and not adherent to the skin. Palpation revealed a cord 4 centimetres long and 1 broad. There were no varices. He diagnosed gumma in the external coat of the external saphenous vein and under specific treatment the patient was relieved in 15 days. Gosselin further observed in a case of secondary syphilis precocious gummata in the cellular tissue and in both internal saphenous veins. Dr. Heuzard, in his *Thèse de Paris*, 1898, describes secondary and tertiary phlebitis; in the former several veins are affected together or one after the other, in the latter the phlebitis may be circumscribed (gumma) or diffuse. Secondary phlebitis affects principally the saphenous veins. It manifests itself at first by congestion which may take the form of red lines corresponding to the course of the veins. Palpation reveals tender cord-like induration of the veins and œdema of the leg. Specific treatment is rapidly successful; sometimes there is a relapse. The veins usually remain permeable. In tertiary phlebitis the veins are sometimes obliterated, sometimes varicose and elongated. Recovery is not always complete; sometimes induration remains.

THE "SATURDAY REVIEW" AND MEDICAL STUDENTS.

WE do not know why the *Saturday Review* should have gone out of its way to indulge in some offensive and insulting remarks regarding medical students as a class, for we do not hesitate to say that the writer's experience in this respect is quite opposed to that of other people who, as far as social position and opportunities for observation and judgment are concerned, are quite as well, and probably much better, qualified to form an opinion. *Apropos* of Mr. G. R. Turner's recent introductory address at St. George's Hospital (in which reference was made to the portraits of medical students in the pages of Dickens and Thackeray as having been drawn from the worst types of a bygone age and in which it was asserted that the behaviour of the London medical students would compare not unfavourably with that of the undergraduates of Oxford and Cambridge) our contemporary gives us the benefit of its experience as follows: "At any rate, we have usually found the medical student to be an individual who combines the maximum of ill-breeding with the minimum of sobriety and who may be generally classified under the genus 'cad,' though doubtless Mr. Turner regards the few exceptions as a hopeful and promising sign for the future." Medical students are drawn from the same social stratum and are educated at the same schools as members of the other professions and they very commonly have relatives in the church, navy and army, law, literature, science, and journalism. These are not "generally classified under the genus cad," although there are doubtless to be found cads, snobs, and prigs among them. Mr. Turner was perfectly justified in saying that the medical profession was now only fit for those with high ideals, good health, good intellects, and a capacity for hard work.

THE RELATION OF THE GROWTH OF THE INFANT TO THE COMPOSITION OF THE MILK.

IN an article contributed to the *Zeitschrift für Physiologische Chemie* (Band xxiv., p. 285) Dr. Pröscher has, at Professor Bunge's suggestion, set himself to corroborate by further research on a large scale an observation made by Professor Bunge himself to the effect that the rapidity of growth in the suckling is dependent upon the proportion of albumin in the milk. Professor Bunge believed he had demonstrated this to be correct in the case of man, horse, cow, and dog. Dr. Pröscher ascertained by experiment, on the one hand, the time required for the newly-born young to double its weight, and, on the other hand, the percentage of albumin in the milk in various animals with the following results. The human infant doubled its weight in 180 days and the percentage of albumin in the mother's milk is 1·86. The foal doubled its weight in 60 days and the milk contained 2·3 per cent. of albumin; the calf in 47 days with 4 per cent. of albumin; the pig in 18 days with 6·89 per cent.; the lamb in 10 days with 7 per cent.; the pup of the dog in 8 days with 8·28 per cent.; and the kitten in 5 days with 9·53 per cent. of albumin in the milk. This law appears also to hold good for the development of the individual. Thus the amount of albumin in human milk on the first and second days after childbirth is 8·6 per cent.; from the third to the seventh day 3·4 per cent.; from the eighth to the fourteenth day and onward during the first three or four months 2·5 per cent., whilst in the second half year after childbirth it falls to 1·6 per cent., which is in correspondence with the gradually falling rate of increase in weight of the infant. In a further series of researches Dr. Pröscher treats of the influence of climate on the composition of milk. He finds from a comparison of a large number of analyses that the milk of animals living in the south of Europe is poor in fat but rich in sugar, whilst the converse obtains in those of the north. The large percentage of sugar in human milk is, he suggests, an indication that man was originally an inhabitant of a warm climate.

THE GORDON BOYS' HOME.

WHILE the reconquest of the Soudan is still fresh in the minds of our readers it is appropriate that we should bring under their notice the institution which is in every sense our greatest national memorial of the heroic Gordon—the Gordon Boys' Home at Chobham. It is satisfactory to learn from an article recently published in the *Charity Record* that the expectations which were founded on the progress of this establishment have not been disappointed. The arrangements within the Home, it will be remembered, are of the most comprehensive character. Provision is made not only for the ordinary course of study as in other schools, but it is amply supplemented by technical instruction—a fact which has probably not a little to do with the success of Gordon boys in after-life. The chapel, which is a Royal foundation in memory of the late Duke of Clarence, and the hospital, containing three wards endowed by Mr. and Mrs. Hamilton-Yatman, are among the most attractive edifices within the grounds of the Home. The boys' band has proved itself a great success and the superintendent, Colonel Walker, has many more applications from the military authorities for boys who have been trained in it than he can satisfy. It is to be noted that due account is taken of any natural bent in the ultimate disposal of the boys. Some particulars given in this connexion are interesting. Up to the present date 363 boys have entered the Army, 20 the Royal Navy, and 14 the mercantile marine; 250 are in civil employ, 13 have emigrated, and 19 have joined the Cape Mounted Rifles. These youths, it is hardly necessary to add, have been rescued from those who often from no fault of their own constitute the broken and wandering wreckage of civilisation. The revelations of juvenile atrocity in Lambeth and elsewhere have shown us what they may become if left to wander. In the results obtained by the Gordon Home we see the converse of that picture. Surely it needs no laboured argument to explain the teaching of this forcible contrast. Hitherto a gratifying measure of support has been accorded to the Home, the popularity of which is, we trust, assured. It is always needful to remember, however, that such a work as that which it carries on cannot be done for nothing, or even at a small

Digitized by Google

cost. As matters now stand the institution can only afford accommodation to 240 boys instead of 360, the number which it is intended to provide for, and it is, moreover, confronted with building and other needful expenses amounting to £2500. Under these circumstances, and in consideration of a past so meritorious and a future so promising, we earnestly hope that the British people in their giving will well remember this eminently practical charity. Lieutenant-Colonel Beatty-Pownall, 20, Cockspur-street, we may mention, will be happy to receive contributions to the Home.

THE CHARITY ORGANISATION SOCIETY AND MEDICAL RELIEF.

AS will be seen from a letter published in another column the Charity Organisation Society have set on foot a course of eight lectures dealing with the subject of medical relief. The fee for attending the course is 5*s*., or for a single lecture 1*s*. The opening lecture will be free. The subjects chosen are certainly of interest to medical men and the names of the lecturers are a guarantee that the various matters will be dealt with by those who have a knowledge of what they speak about.

THE PLAGUE IN INDIA.

THE latest returns from India for the week ending Oct. 8th show no decrease of plague for Bombay city and Presidency. The epidemic continues to spread at Bangalore, where 371 cases have occurred since Sept. 28th last. The disease also still prevails at Karachi and to a slight extent in some Madras districts. Calcutta, which has hitherto suffered but little, is now, we are glad to say, officially declared free from plague, no cases having occurred there for ten days. The local government and municipal authorities are wisely alive to the fact, however, that experience has shown that the accession of cold weather is apt to be accompanied by a renewed activity of the disease and are consequently not relaxing their precautionary measures.

MORBID ANATOMY OF YELLOW FEVER.

IN the *Medical News* (New York) of Sept. 3rd Dr. Eugene Wasdin gives a detailed account of the results of numerous necropsies which he has performed in cases of yellow fever and makes some interesting observations as to the post-mortem diagnosis of this disease. He remarks that the yellow fever cadaver has certainly a most characteristic appearance. All subjects dead from the disease bear a close resemblance to each other; indeed, it would not be difficult to make a diagnosis, other facts being favourable thereto, from the cadaver alone. Post-mortem rigidity comes on early and persists. The colour is invariably more or less intensely yellow, which is due to a mixed hepatogenous and hæmatogenous jaundice. This yellow tint is always contrasted with the deep purple discolourations from hypostasis which quickly appear in the skin of the dependent portions of the body after death. Dr. Wasdin's experience in necropsies in subjects dead from malarial fever in the South has shown him that there are externally many points of resemblance in them to the yellow fever cadaver, and he feels assured that at times the decision between them would be very difficult or even impossible. Dependence must then be placed upon the conditions found in the internal organs. A good account is given of the changes which are seen, but which we have not space to notice here. He draws attention to a very notable congestion of the vasa vasorum of the great vessels at the base of the heart, these minute vessels forming a delicate tracery over the serosa and upon the walls of the auricles, which at times present minute ecchymoses. Dr. Wasdin deems this a very constant and characteristic appearance. He further says that a yellow fever necropsy is usually considered to be a bloodless one, but this is by no means the case. In reality, the full influence of the toxin falls upon the vaso-motor system and results in an incomparable congestion of the vessels of the abdomen and when complete the section presents an appearance quite the reverse of bloodless. The question naturally arises as to the diagnostic value of the conditions described in this paper. Is it possible to arrive at definite conclusions from an isolated case presenting all the signs usually found in cases of death from yellow fever? Should we be justified in such cases either in withholding quarantine protection from a community or in initiating quarantine to the possible detriment of commerce? From his recent observations Dr. Wasdin feels safe in asserting that it is not possible to diagnose this disease from the post-mortem appearances and the gross microscopic findings alone. He does not undervalue their importance, when taken in due consideration with the history of the case, the clinical charts, and the history of albuminuria, in assisting the observer to form an opinion, but in the absence of these accompanying facts they are not sufficient to enable him to name the disease, although a diagnosis may be safely ventured upon in the absence of any other known cause of infection.

FEMALE HEALTH VISITORS AS AIDS TO SANITARY PROGRESS IN MANCHESTER.

WHAT may be termed the lay element in sanitation is not always an unmixed blessing, but if this force can be kept within proper channels much good may conceivably result from it. Such at any rate is apparently the lesson to be learnt from the efforts of the Ladies' Health Society in the city of Manchester, an organisation which was started in 1862. The health visitors of this society live in their respective districts and each devotes six hours daily (Saturdays excepted) to visiting, a report of the work done being received each morning by the medical officer of health. Amongst the duties devolving upon the visitors is to supply lime for limewashing, and the loan of brushes, &c., for use; and as an instance of what is done in this direction Dr. Niven tells us that one visitor alone succeeded in bringing about in 1897 the limewashing of 50 bedrooms as well as numerous sculleries, kitchens, &c. In the matter of advice and guidance the visitors are most active, and much burning of refuse, washing of clothes, &c., is done under their supervision. They are the bearers of disinfecting powder and of printed instructions concerning the feeding of children, while any sanitary defects which they discover on their rounds are at once reported to the medical officer of health. The promotion of ventilation is naturally within their province and the fact that one visitor sold 50 blocks of wood for fitting beneath the lower sashes of windows will afford an indication of the success of their efforts. In a word, their work is, in the main, educational, and everyone familiar with the conditions of the poor in our large towns knows the importance of a movement such as this.

THE CAUSE OF THE DEATH OF GEORGE II.

AT a time when England was resounding with proclamations of naval and military glories George II. died suddenly at Kensington from a rupture of the right ventricle of the heart whilst preparing for a walk in the gardens. This was on Oct. 25th, 1760. In the *Phonographic Record* for October of the present year Dr. G. F. Atchley publishes a reprint from the *Royal Magazine* of 1760 giving an account of the necropsy made upon the body of the King. The report is dated Kensington Palace, October 16th (*sic*), 1760, and is as follows:—"In obedience to the order transmitted to us by the Rt. Hon. Mr. Vice-Chamberlain,

Digitized by Google

we, the undersigned, have this day opened and examined the body of his late Majesty, in the presence of Sir Edward Wilmot, Bart., and Dr. Nicholls, two of his late Majesty's physicians; and first on opening the belly we found all the parts therein contained in a natural and healthy state, except only that on the surface of each kidney there were some hydatids or water bladders, which, however, we determined could not have been at this time of any material consequence. On opening the breast we observed the pericardium or bag which contains the heart extremely distended, which was owing to a large effusion of blood that had been discharged therein from a rupture in the substance of the right ventricle of the heart. The quantity of the blood in the pericardium was at least a pint, the most part of which was strongly coagulated. The rupture of the ventricle and the consequent effusion of blood in the pericardium were certainly the immediate cause of his late Majesty's sudden death. The brain, lungs, and all the other parts were in a perfect state. (Signed), E. Wilmot, John Ranby, Fr. Nicholls, and C. Hawkins."

ANTI-RABIC INOCULATION IN BRAZIL.[1]

DURING the eleven years which elapsed from the opening of the Pasteur Institute at Rio de Janeiro in February, 1888, to the end of last April 3973 persons presented themselves for treatment, but of this number no fewer than 1326, or 33 per cent., were refused admission chiefly because it was found that the animals they had been bitten by were not suffering from hydrophobia; and after the treatment had been inaugurated there was, for various causes, a further elimination of 106 cases. The number of persons who underwent the preventive process in its entirety was consequently 2541, and amongst these there were 20 deaths from hydrophobia, a percentage equal to 0·78. In view of the pains taken to exclude all illegitimate cases this would seem to be a sufficiently satisfactory death-rate, but in the opinion of Dr. Ferreira dos Santos, the Director of the Institute, the true rate was considerably lower. 9 of the 20 deaths occurred within a fortnight of the final inoculation—that is, before the protective influence of the injected virus had had time to become fully established, and he contends that these should on that account be withdrawn from the calculation. In that case the "definitive statistics" of the first decade of the Rio de Janeiro Pasteur Institute would read as follows: Number of persons treated, 2532; deaths, 11: percentage of fatal cases, 0·43. Generally speaking the mode of procedure adopted at the Brazilian institute is precisely the same as at the Parisian, only a few slight modifications as o matters of detail having been introduced by Dr. Ferreira dos Santos. The inoculations take place at 8 o'clock in the morning, but in urgent cases a second inoculation may be administered at 5 o'clock in the afternoon for a few days at the outset of the treatment. The marrows employed for first inoculations are of fourteen days' standing, and for the last of three days'. In dangerous cases, however, more especially when the temperature of the air exceeds 70° F., thus conducing towards rapid desiccation, the final inoculation of the series should be performed with a second-day marrow. The virus now in use was derived from rabbits which were inoculated in Paris in July, 1887, and since then has passed through 360 sets of these animals without a break, the rabbits invariably developing symptoms of the disease on the sixth day. Instead of veal broth a 1 per cent. solution of chloride of sodium in filtered sterilised water is used, and the director maintains that he thereby almost entirely obviates pain even in the most sensitive of his subjects. The following compressed statistical items will be found interesting. Out of the 2647 persons who were accepted for treatment only 96 had been efficiently cauterised, although in 1900 cases the bites were inflicted on exposed parts. In 236 of the attacking animals hydrophobia was experimentally proved to be present, and in 1173 more the symptoms exhibited during life were pathognomonic of the disease. 59 of the persons who presented themselves at the institute withdrew on learning the nature of the treatment, one of them subsequently dying from hydrophobia. 65 individuals left the institute prematurely after commencing the treatment, and of these 3 died from the same disease; 6 patients developed hydrophobia while undergoing the inoculations, 5 of them having been bitten in the head. Among the rejected applicants there were 51 persons who presented more or less severe contusions but no abrasions or other solutions of continuity, and also 9 who came because they had been bitten by animals which subsequently became rabid.

THE MIDLAND MEDICAL SOCIETY.

THE Midland Medical Society attained its jubilee this year and in order to celebrate this event a dinner was held at the Grand Hotel, Birmingham, on Thursday, Oct. 6th. Mr. J. W. Taylor, president of the society, was in the chair and the company included Sir William Mac Cormac (President of the Royal College of Surgeons of England), Sir Benjamin Stone (M.P. for East Birmingham), the Right Rev. E. A. Knox (Bishop of Coventry), Mr. T. H. Russell (the President of the Birmingham Law Society), and many prominent members of the medical profession. Sir William Mac Cormac proposed the toast of the evening and spoke with enthusiasm of the success and ability of Birmingham medical men. Of the Birmingham General Hospital he said that "as far as his humble judgment went he thought that not even in London was there any hospital equal—he would not say superior, but not one equal—to the hospital which Birmingham now possessed. Everyone connected with the hospital might be congratulated, as well as the town to which the institution belonged." This is high praise, but there is no one better fitted to give such an opinion than the President of the Royal College of Surgeons of England, for he has had opportunities of seeing hospitals in every capital in Europe, while, as reference to our columns will show, he is indefatigable in his visits to the institutions of our provincial capitals.

ANTI-VIVISECTIONISTS AT BRADFORD.

DURING the recent Church Congress at Bradford the Church Anti-Vivisection League called a meeting at which the chair was taken by the Rev. T. Perkins. The reverend gentleman made a speech of a curious character for a chairman, for it was throughout a strong indictment of the practice of vivisection. Mr. Perkins has, of course, every right to his own opinions, but we should have thought that the duty of a chairman was to be impartial. Be this as it may, Dr. Hime proposed the following resolution, which was carried by an overwhelming majority:—

"That in the opinion of this meeting human interests are of paramount importance as compared with those of other living creatures, and therefore we are justified in utilising the lower animals for the preservation of human health and life, all unnecessary suffering being avoided."

We have on a previous occasion had a passage of arms with the Church Anti-Vivisection League concerning a leaflet which it circulated in regard to Hospital Sunday. In THE LANCET of June 6th, 1896, will be found a reply from Miss Woodward, the secretary, to an annotation published in our columns on May 30th, 1896. It will be seen by the leaflet issued by the League that information and proof will be supplied to any of the clergy who may

Digitized by Google

doubt the assertions of the League. We applied for proof, but unless Miss Woodward's letter can be considered as such we did not procure it. A second appeal has also failed to get any information from Miss Woodward—but then we are not clergy. We are, therefore, reluctantly compelled to the belief that the Church Anti-Vivisection League is one of those secret societies with which the Church, according to a recent correspondent in the *Times*, is honeycombed. A society which only supplies information to the clergy is evidently sacerdotal to a most dangerous degree.

YELLOW FEVER IN AMERICA.

THE situation caused by the spread of yellow fever in the state of Mississippi is somewhat threatening. There have been 470 cases and 36 deaths in the state since the outbreak of the disease. It is curious to notice the interdependence existing between sickness and commercial interests. The price of several of the United States railroad shares in the London market was no doubt affected by the reports of the spread of the yellow fever epidemic in the South. It seems probable, however, that the accession of colder weather in Mississippi will repress the spread of the disease and allay the fears entertained that the entire State will be infected.

THE FRIENDLY SOCIETIES AND THE GENERAL MEDICAL COUNCIL.

WE gather from a paragraph in the *Times* that at a conference of the leaders of friendly societies the interim report of the General Medical Council on Medical Aid Associations was under discussion. A sub-committee was appointed to go into the whole subject, from which we may hope for the existence of a desire on the part of the friendly sòcieties to adopt reasonable proposals for the adjustment of differences between them and the medical profession.

MISLEADING ADVERTISEMENTS AND SCIENTIFIC CRITICISM.

A CASE of great interest and importance with regard to the publication of scientific criticism of proprietary articles has recently been decided in France. The decision was arrived at in March last, but was not publicly known until a certain time for appeal had been allowed in accordance with the requirements of French law. The findings of the court have recently been made public. The facts of the case are briefly as follows. A firm of opticians in Paris were the proprietors of a glass containing baryta, from which lenses described as "isometropic" were prepared. With the view of testing the statements made in favour of those lenses by the proprietors, Dr. Javal, the director of the Ophthalmological Laboratory of the Sorbonne, instructed his assistants to make a careful examination of the glass and lenses and to report to him the results. Subsequently these results were published and presented to the French Academy of Medicine, the conclusion being that the differences between baryta glass and ordinary glass were insignificant; there was nothing in favour of the former, and the "isometropic" lenses did not offer any advantages to purchasers. The proprietors brought an action for damages to the extent of 20,000 francs, but the court decided that a scientific man might rightly examine and criticise on public grounds any manufactured article for which special merits were claimed, and they found for the defendant upon all the issues, condemning the plaintiffs in costs. Nothing could be more satisfactory than this decision and we could wish to see this example followed in this country. How instructive and useful to the community at large would it be if the Fellows of the Royal Society or the Chemical Society could leave abstruse pursuits for a while and present papers, say, on the composition of "Munyon's Remedies," "Pink Pills," "Siegel's Syrup," "Blood Mixture," "Microbe Killer," and so on *ad nauseam*. Could, indeed, this be realised we might at last hope that the scales would be removed from the eyes of a remarkably gullible public.

RELAXATION OF MUSCLES IN ORGANIC HEMIPLEGIA.

IN 1896 M. Babinski read a paper on this subject at a meeting of the Société de Biologie. He observed in several cases of hemiplegia and monoplegia due to a cerebral lesion a relaxation of muscles which allowed passive movements in the affected limbs of greater extent than in the sound. His observations particularly refer to the degree of passive movement of flexion of the forearm, which could be carried to a greater extent on the paralysed side. He observed this phenomenon at first in recent cases of hemiplegia with flaccid paralysis without increase or with decrease of tendon reflexes. In a case of twenty hours' duration when the legs were hanging the angle formed by the foot with the leg was greater on the paralysed side; when the forearms were horizontal and pronated flexion of the hand was also greater on this side. In none of the cases was there amyotrophy. Afterwards he observed this phenomenon in several cases of hemiplegia of several months' duration with exaggeration of reflexes. M. Babinski thinks that the phenomenon is of the same nature as the drooping of the angle of the mouth which is observed in hemiplegia; it is due to a loss of tonicity of muscles. It is somewhat singular that relaxation of muscles should occur with exaggerated reflexes. In the various cases of hysteria which he observed since his attention was directed to the phenomenon it was absent. He is therefore led to believe, without being dogmatic, that it may serve to distinguish organic from hysterical monoplegia and hemiplegia.

THE TREATMENT OF SPASMODIC TORTICOLLIS.

IN the *Boston Medical and Surgical Journal* of August 18th, 1898, Dr. H. J. Hall relates two cases of spasmodic torticollis—one cured and the other much relieved by the use of a spring to press on the cervical muscles. A woman, aged thirty-six years, was seen five months after the onset of spasmodic torticollis. Whilst recumbent there were no unnatural movements of the head, but on sitting up rhythmic contraction of the right sterno-mastoid muscle and of all the posterior rotators and retractors began. The head was turned with much force to the left and was markedly retracted. He observed that a firm grasp of the hand on the neck greatly diminished the spasm. The application of a spring clamp to the back and sides of the neck at once decreased and controlled the spasm, which recurred on removal of the pressure. The clamp was of simple construction, being made of light spring steel broader than, but similar to, that used as trousers' guards by bicyclists. A tail-piece ran from the middle of the spring about 6 in. down the back so as to keep it in position. A gentle pressure was thus exerted on the back and sides of the neck as far forward as the anterior border of the sterno-mastoid muscles. After a month the spring could be discarded for several hours a day. As a final result there remained slight painless and fixed left torticollis due to permanent contraction of the affected muscles, but the patient could turn her head freely and there was no retraction. The second was a severe case of five weeks' duration which was relieved at once and in three months was practically cured by the clamp and gymnastic exercises.

THE opening lecture of the winter session of the Hospital for Consumption and Diseases of the Chest, Brompton, will be on Aneurysm of the Aorta, and will be delivered by

Digitized by Google

Dr. Mitchell Bruce on Wednesday, Oct. 19th, at 4 P.M. The lecture is open to students of the hospital and to all qualified members of the medical profession. The forthcoming lectures will be announced week by week in our Medical Diary.

THE annual public night of the Medical Society, University College, London, will be held on Oct. 19th, when an address will be delivered by Professor F. T. Roberts, M.D., F.R.C.P. Lond., on "The Personal Factor." The chair will be taken at 8 P.M. by the President, Dr. H. Batty Shaw. There will be an exhibition of Medical and Surgical Appliances.

AT the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on Oct. 11th, Dr. W. H. Lloyd, Inspector-General, in the chair, the sum of £56 was distributed among the several applicants.

HENRY ALFRED ALFORD NICHOLLS, M.D. Aberd., C.M.G. (medical officer of the public institutions), has been appointed an Official Member of the Legislative Council of the Presidency of Dominica.

THE OPENING OF THE THOMPSON-YATES LABORATORIES AT LIVERPOOL.

LIVERPOOL on Saturday last, Oct. 8th, was the scene of two imposing ceremonies—the opening of the Thompson-Yates Laboratories of Physiology and Pathology by Lord Lister and the conferring upon the founder of antiseptic medicine the degree of Doctor of Science of the Victoria University. The two ceremonies were blended into one by the happy management of the authorities of University College, Liverpool, who thus displayed for the consideration, not only of scientific men and not only of Liverpool, but of all civilised and progressive communities, a highly impressive event. When the Rev. S. A. Thompson-Yates furnished the noble sum of money necessary for the erection of these laboratories and also came forward, as he did, to meet the great additional expenses necessary to provide furniture for them and equip them from top to bottom with every fitting and every instrument known to modern science as useful either in educational work or in the most recondite and speculative departments of research, it was felt that one man was marked out as the right person to declare the buildings open to students for the advancement of science in general and of scientific medicine in particular—that person was Lord Lister. It was therefore with great pleasure that Liverpool—the city every whit as much as the University College—heard that the President of the Royal Society was able to fall in with their unanimous wish and perform the opening ceremony, while the opportunity was readily seized by Victoria University to do honour to Lord Lister, and to themselves, by conferring upon him the honorary degree of Doctor of Science.

THE CONFERRING OF A DEGREE UPON LORD LISTER, P.R.S.

At three o'clock on Saturday afternoon St. George's Hall was an imposing sight, being crowded with an assembly representative of all the prominent classes in Liverpool, academic, political, social, professional, and commercial, who had gathered together to see the degree of Doctor of Science of Victoria University conferred upon Lord Lister—the first degree, we believe, which has been conferred by the University in Liverpool. Shortly after three a procession of gentlemen who for the various reasons suggested by their names, which will be for the most part familiar to our readers, had been invited by Victoria University to be present, walked slowly up the body of the Hall to the strains of one of the finest organs in the world and took their seats upon the platform. The following is the official list of the procession, and but very few of those invited failed to be present, a fact which, when the serious nature of the daily work of many of these gentlemen is remembered, makes it manifest that there must have been a general feeling abroad that the occasion was one of more than ordinary significance. All the members of the procession were in full academic attire, and the prevailing hue of scarlet signifying the doctorate of science or medicine was gorgeously diversified by hoods and facings of every tint. The procession was headed by the Vice-Presidents of University College, Liverpool, Mr. W. Rathbone and Mr. Edward Lawrence, after whom came the following in order:—

The College Council.—Mr. Alsop, Canon Armour, Mr. A. Booth, Mr. R. Gladstone, Mr. C. W. Jones, Mr. E. K. Muspratt, Mr. George Rathbone, Sir Edward Russell, and Mr. A. F. Warr, M.P.

The Registrar.—Dr. Londini.

The Chairman of the School of Commerce.—Mr. P. E. J. Hemelryk.

The Chairman of the School of Architecture.—Mr. Hartley.

The Chairman of the Board of Legal Studies.—Vice-Chancellor Hall, Q.C.

Honorary Members of the Staff.—Dr. Lloyd, Mr. Parker, Dr. Dickinson, Dr. Nevins, and Dr. Waters.

Emeritus Professors.—Professor Mitchell Banks, Professor Caton, and Professor Davidson.

Guests.—Professor Dunstan, Mr. P. M. Smith, Professor Kauffmann, Mr. A. Cope, Mr. Bokenham, Professor Thompson, Professor Vaughan Harley, Mr. James Ritchie, Professor Oliver, Dr. Leonard Hill, Professor Meldola, Professor Bower, Mr. Ballance, Mr. Stiles, Professor Rose Bradford, Professor Finney, Professor Murray, Dr. Noel Paton, Professor Allen, Mr. W. Thorburn, Dr. Sims Woodhead, Professor Poulton, Dr. Mott, Dr. Isambard Owen, Dr. W. Hunter, Dr. S. Sprigge, Professor Marshall Ward, Mr. Makins, Dr. Dawson Williams, Professor Purser, Professor Coats, Dr. Pavy, Dr. Ferrier, Dr. Copeman, Professor Cunningham, Mr. Scott Keltie, Dr. Saundby, Professor Hamilton, Dr. Bastian, Sir Henry Littlejohn, Professor Schäfer, Professor Forsyth, Mr. W. F. Lawrence, M.P., Dr. Gaskell, the Mayor of Birkenhead, Sir R. Thorne Thorne, the Mayor of Bootle, the Mayor of Preston, Mr. Ashton Bostock, Professor Rücker, Mr. A. T. Bentley, Professor T. R. Fraser, President of the Medical Institution of Liverpool (Dr. Macfie Campbell), Dr. Bickersteth, Professor Waller, Professor Crookshank, Professor Yeo, Professor Kanthack, Principal Lloyd Morgan, Principal Heath, Principal Reichel, Sir James Russell, Dr. Isaac Roberts, Mr. Alfred Waterhouse, R.A., Mr. G. Rodie Thompson, Mr. Heywood Thompson, Professor Rutherford, Dr. Lauder Brunton, Mr. R. D. Holt, Dr. Rendall, Mr. Justice Kennedy, the Vice-Chancellor of Cambridge University (Dr. A. Hill), Sir J. Crichton Browne, Captain Abney, Sir D. Calton, Professor Gotch, Sir A. Geikie, Sir W. Gairdner, Mr. E. P. Thompson, the President of the Royal College of Surgeons of Edinburgh (Professor John Chiene), Lord Kelvin, the President of the Royal College of Physicians of Edinburgh (Sir J. Batty Tuke), the Bishop of Carlisle, Sir William Turner, Professor Michael Foster, the Bishop of Chester, Mr. R. B. Haldane, the Bishop of Liverpool, Professor Burdon Sanderson, the President of the Royal College of Physicians of London (Sir S. Wilks), and Professor Virchow.

Assistant Lecturers and Demonstrators of University College.—Dr. Abram, Dr. Armour, Dr. Buchanan, Mr. Cole, Mr. Douglas Crawford, Dr. R. C. Dun, Dr. Grünbaum, Mr. A. G. Gullan, Mr. C. E. Jones, Dr. Hugh R. Jones, Mr. Lovegrove, Dr. Manby, Mr. Marsden, Mr. Nelson, Dr. Stockdale, Mr. Stratton, Mr. Thelwall Thomas, Dr. Titherley, Dr. A. J. Wallace, Dr. Warrington, and Mr. Woods.

College Lecturers.—Dr. Barr, Mr. Councell, and Mr. Phillips.

The Librarian of the College.—Mr. Sampson; after whom walked a group of University graduates of less than three years' standing.

Convocation.—Mr. Stuart, Miss Marsland, Mrs. Brown, Mr. Hardwick, Miss Broadbent, Miss Sandford, Mr. W. E. Livsey, Mr. Lackland, Mr. J. Jones, Mr. Clubb, Mr. Winstanley, Mr. O'Hagan, Mr. W. E. Hoyle, Mr. W. P. Steinthal, Miss Ellis, Dr. Coutts, Miss Auld, Mr. F. E. Taylor, Dr. J. H. Shaw, Miss Roper, Mr. J. C. Quinn, and the Rev. C. C. Lundie, Mr. A. Carey, Miss Buckley, Dr. Martin, Dr. Gilbody, Dr. Kelynack, Miss Crompton, Mrs. Ashburner, Mr. C. T. Needham, Mr. A. Schloesser, Mr. Willis, Mr. Charles Hughes, Dr. Pierce, Rev. C. T. Poynting, Dr. Rayner, Mr. J. H. Thompson, Mr. W. R. Innes, Miss C. D. Tennant, Dr. Gerland, and Mrs. Tout.

University Lecturers.—Mr. O. Elton, Dr. Friedel, Mr. Hebblethwaite, Mr. Woodward, Mr. Gwyther, Dr. T. L. Bailey, Mr. Hay, Dr. Howard, Dr. Kohn, Mr. Sharpe, Mr. Stanton, Mr. Owen, Mr. Edgar Browne, Dr. Peter Davidson, Dr. Wiglesworth, Dr. Campbell, Dr. Hellier, Mr. Ward, and Dr. Hiles.

Professors.—Faculty of Arts: Professors Alexander, Davies, Gonner, Mac Cunn, Mackay, Meyer, Raleigh, Simpson, and Strong. Faculty of Science: Professors Core, Dixon, Hickson, Lamb, Campbell Brown, Carey, Harvey Gibson, Hele-Shaw, Herdman, Lodge, and Beaumont. Faculty of Law: Professor Emmott. Faculty of Medicine: Professors Delépine, Dreschfeld, Jones, Leech, Dixon Mann, Sinclair, Stirling, Young, Carter, Glynn, Hope, Rushton Parker, Paterson, Paul, De Burgh Birch, Hartley, Trevelyan, Wright, Boyce, and Sherrington.

External Examiners.—Professors J. Reynolds Green, Halliburton, and S. Martin, Mr. Bilton Pollard, Professors Symington and Walker.

University Court.—Miss Cook, Mr. N. Clegg, Mr. W. Mather, Rev. J. Sephton, and Sir Francis Powell.

The Chairman of the Board of Studies.—Professor Tout.

The Principal of Owens College.—Mr. Alfred Hopkinson.

The Principal of University College.—Mr. R. T. Glazebrook.

The Vice-Chancellor of Victoria University.—Principal Bodington.

The Pro-Vice-Chancellor.—Professor Wilkins.

Immediately behind the Pro-Vice-Chancellor came Lord Lister in the robes of his new degree, followed by the stately

Digitized by Google

figure of Earl Spencer in the blue and gold of his official position as Chancellor of the Victoria University.

The Registrar, Mr. Alfred Hughes, brought up the rear.

Lord SPENCER opened the proceedings in a dignified and sensible speech. He recalled briefly the benefactions which University College, Liverpool, had received during its comparatively short life from Liverpool men and referred to Mr. Thompson-Yates's splendid munificence as "putting a magnificent crown in a magnificent manner upon the proceedings of his fellow citizens." Coming then to the particular purpose for which the assembly was present in St. George's Hall—namely, the admission of Lord Lister to the degree of Doctor of Science of the Victoria University—Lord Spencer held that it would be unbecoming in him to enlarge upon the merits of the President of the Royal Society, particularly as the gentleman who would shortly introduce his lordship to receive his degree would necessarily allude to his great public and scientific claims, but, he concluded, "we of the Victoria University feel with one of the most distinguished men of science in the world, Professor Virchow, that in saluting Lord Lister with enthusiasm we are honouring a man whose career has been one of conspicuous glory here and all over the world."

Dr. CATON, Emeritus Professor of Physiology in University College, Liverpool, and late Dean of the Medical Faculty, then pronounced an eloquent panegyric upon Lord Lister's work. "Possessing a heart and mind," he said, "full of sympathy, benevolence, and humanity, our visitor of to-day, from an early period of his career as a surgeon, witnessed with pain and sorrow the mortality and suffering which was wont to attend surgical injury and disease in man and no less in the lower animals. He determined to devote his life to an inquiry into the causes of this suffering and mortality and brought to his task scientific abilities and knowledge of the highest order, and in particular a profound acquaintance with the work of Pasteur, the great French observer. After long years of patience and conflict with difficulties he was privileged, not only to discover the cause of all this suffering, but also the remedy. To-day there is not a hospital in the civilised world which has not been transformed through Lord Lister's teaching and in which death and suffering have not been to a very large extent banished. To-day there is not a case of serious surgical disease or surgical operation in man or woman in any rank of life, or even among the lower animals, in which Lord Lister's work has not diminished the liability to suffering and death. The work of Lord Lister is of extraordinary value in time of war. The field and base hospitals for the wounded were in former times the scene of a mortality from septic fever far greater than that occurring in the field. But how is it now? The Director-General of the Royal Army Medical Corps has recently said that during and after the recent war in the North-West Provinces of India not one single case of septic fever occurred. Formerly as many as one-half of the wounded succumbed to this cause. Lord Lister has doubled the utility of the work of the surgeon and lightened the burden of pain and death. Work of this order is far above recompense or reward; the nobility of such a life is for us to imitate rather than to praise. But still the court and council of our University desire to confer on Lord Lister the degree of doctor of science, in recognition of the fact that never has science been more nobly enlisted in the cause of humanity and of human progress than in the work of his life."

Lord LISTER was then formally presented to the Chancellor amidst loud and prolonged applause and signed the roll of the Victoria University.

Mr. R. T. GLAZEBROOK, the recently appointed Principal of University College, then made a brief statement concerning the new laboratories, the opening of which was the primary object of Lord Lister's visit to Liverpool. Mr. Thompson-Yates, he said, came forward in 1894, when it was clear that the work of the professors of physiology and pathology, whose chairs had already been endowed by the generosity of the late Mr. George Holt, was being seriously hampered for want of rooms in which to lecture and laboratories in which to work. He then offered to build the laboratories and theatres. The structure cost £18,000. A second gift was made immediately afterwards of £6000 for furnishing the building and a final gift rapidly followed of £4000 for apparatus, the noble sum of £28,000 in all. Principal Glazebrook concluded, amidst applause, by reminding his audience that there was still scope for their generosity in many directions, and his words had all the more weight from the fact that he was able to speak not only as Principal of the College but as a late assistant director of the Cavendish Laboratory at Cambridge.

LORD LISTER'S ADDRESS.

Lord LISTER then read the following brief address:—

My Lord Chancellor, my Lord Mayor, my lords, ladies, and gentlemen,—When I was honoured by the authorities of the Liverpool College with the request that I would open the Thompson-Yates Laboratories I little imagined that I was asked to take part in so imposing a ceremonial as the present. That it should have attracted so large and brilliant a company seems to me a matter of great importance, full of good augury for the future of the scientific practice of the healing art; in other words, of treatment based on real knowledge as contrasted with the blind gropings of empiricism. We have before us to-day evidence that the cultured sections of the British public are alive to the necessity of providing adequate means for the practical study of the knowledge which confers the power to recognise and treat disease. If an engineer is to qualify himself for detecting and correcting anything wrong in a machine of human construction no verbal description or drawings will give him the requisite information; he must see and handle the details of the mechanism and watch them at work. And it might seem the veriest common sense that the more practically familiar a man is with the structure and working of that marvellously complicated mechanism, the human body, the better fitted will he be to deal with its disorders. Yet, obvious as this is, it is only in recent periods that its truth has been generally recognised. I am old enough to remember the years before the passing of the Anatomy Act, and I recollect being told as a child of the fiendish deeds of Burke and Hare—horrors which, it would appear, were needed to arouse a prejudiced and apathetic public to the imperious necessity of making it legally permissible for the intending surgeon to become acquainted in the only possible way—i.e., by dissection—with the sacred structures which he would be called upon to invade with his knife. A dissecting-room well provided with the needful material for study has since been an essential equipment of every medical school, and a thorough course of dissection is demanded of every medical student. Meanwhile, another kind of anatomy than that which the scalpel displays has come into being — the anatomy which the microscope has revealed and is revealing. This microscopic anatomy, both of healthy and of diseased structures, has assumed the greatest importance and requires special provision for its successful study. The materials to be studied cannot well be obtained by the student in his lodgings, and the processes involved in the study are often of a complicated character which he cannot learn unaided and which require more costly apparatus than he can provide. The requisite facilities for this work will be amply supplied by the laboratories which are to be opened to-day. The necessity for special pathological institutions has long been recognised on the Continent, and nowhere has such an establishment been conducted with more signal success than in the Pathological Institute of Berlin, which has been presided over for many long years by the illustrious man whom Liverpool is, I am sure, as glad to welcome with reverence as London has been. Many present to-day have sat at the feet of Professor Virchow, but we may fairly anticipate that Liverpool students, at all events, will for the future be able to dispense with pilgrimages to Germany. While the minute anatomy of normal and morbid structures will be thus effectively taught in the new laboratories much may also be done in them to demonstrate and explain the actions of the living organism. I well remember the effect produced upon me, as a member of Dr. Sharpey's class in London, by the repetition before us of Bernard's great experiment on the local circulation. The sympathetic nerve in the neck of an animal being divided, the ear of that side instantly became red and hot and the blood-vessels turgid, while on the application of galvanism to the severed nerve the opposite effect immediately followed, the ear becoming white and cool and the vessels less conspicuous than those on the other side. Thus was impressed upon us, as mere oral teaching could hardly have done, the immensely important fact that the contractions of the arteries are as much under the control of the nervous system as are those of the muscles of a limb. I need, perhaps, hardly add that the animal being completely under an anæsthetic during such a demonstration no pain whatever is inflicted. In the study of the new science of bacteriology the pathological laboratory will render most

Digitized by Google

important service. The student will see with his own eyes by aid of the microscope the minute living beings which we now know to constitute the essential cause of many infectious diseases and he will learn to "cultivate" these microbes, which, while it will impress upon him the reality of their existence and the characters by which the various species may be recognised, will be invaluable as an exercise of the habits of accurate observation and manipulative skill. The new laboratories will also serve as a centre to which practitioners of a wide surrounding district may refer for the authoritative determination of the nature of doubtful specimens of diseased materials which they have neither the needful equipments, time, nor special knowledge to decide for themselves. As important as the services which the laboratories will render to the education and medical practice will be the opportunities which they will afford for research. I had occasion, in the address which I gave two years ago in this city, to refer to some of the benefits which have been secured to mankind by recent biological investigation, and I need not say more on the subject at present; but I would remark that every step in advance in science only opens up wider fields for exploring the infinite resources of nature, and these laboratories will afford ample means for the further prosecution of such beneficent inquiries. Some, perhaps, may be disposed to object to such researches because they involve the sacrifice of animal life. This, however, I need hardly remark, is as nothing compared to what occurs for the supply of food to man. Of animal suffering I need hardly speak because, in truth, the actual pain involved in these investigations is commonly of the most trifling description. Anæsthesia has come to the aid of experiment on animals and enables needful operations to be performed without disturbance from the struggles of the animal, while it affords to the operator the unspeakable comfort of knowing that he inflicts no pain. I am bound to add that antiseptic treatment of the wounds has had a similar doubly beneficial influence; by preventing inflammation it renders healing painless, while it leaves the parts uncomplicated by inflammatory changes and allows the results of operative procedure to be rightly estimated. I greatly surprised a former Chancellor of the Exchequer when, on a deputation to him on this subject, I explained to him that operations for the removal of parts of the brain of monkeys, which he had imagined to be attended with horrible torture, had, thanks to anæsthetics and antiseptics, been probably from first to last unattended with a twinge of pain. Such operations thus painlessly conducted have, by indicating the precise function of different parts of the organ and thus guiding the surgeon in his operations, already led to the saving of many human lives. While I deeply respect the humane feelings of those who object to this class of inquiry I assure them that if they knew the truth they would commend and not condemn them. The laboratories, though they will be formally opened to-day, have for some time been in practical operation, with the result that the Biological and Pathological School of Liverpool is ranking very high among similar institutions in other parts of the world. As an illustration I may mention the fact that a committee of the Royal Society, acting with the approval of the Secretary of State for the Colonies, has lately selected a pupil of this school as one of two men specially qualified to undertake investigations in Africa on the deadly malaria of those regions. I cannot conclude these remarks without congratulating the Liverpool College on the mighty addition which these laboratories afford to its powers for usefulness. I believe they may be pronounced, both in structure and equipment, equal to any in existence. I must also congratulate you on having so nobly generous a benefactor as Mr. Thompson-Yates. I trust he will be rewarded by the deep satisfaction of knowing that he is doing incalculable good to mankind. If I may make one more observation it is that while these institutions have been so nobly constructed and equipped there is yet much to be desired as regards the means for maintaining them in efficiency. And if any wealthy inhabitant of Liverpool is anxious to bestow his wealth in some manner calculated to do good to his fellow-men he could hardly do better than by devoting a portion of his resources to the permanent maintenance of these fine institutions.

The LORD MAYOR of LIVERPOOL (Mr. Alderman John Houlding), in the absence of the Earl of Derby through a family bereavement, then proposed a vote of thanks to Lord Lister for his address, which was seconded by Mr. WILLIAM RATHBONE and passed with acclamation.

THE OPENING OF THE LABORATORIES.

The proceedings in St. George's Hall terminated with a few words of graceful thanks from Lord Lister for the cordiality with which he had been received, and the company adjourned to University College for the opening of the laboratories. Most of the guests and official representatives of various public and scientific bodies elected to walk from St. George's Hall to the College in their full academic costume, and the outward signs of the doctorates of science and medicine formed a decidedly conspicuous picture in the streets and one which afforded considerable excitement to the citizens. The College being reached the formalities connected with the opening of the laboratories were commendably brief. Mr. Lawrence, a Vice-president of the College, presented Lord Lister with a gold key and asked him to unlock the door closing the main entrance to the building and declare it open. This being done the company made a tour of inspection of the laboratories, which have been described so recently in the columns of THE LANCET that nothing more need be said of them here save to register the opinion of all that in completeness and convenience they have not their superior in any centre of education. Tea and coffee were then served in the College to a very large concourse of guests who afterwards dispersed.

THE LORD MAYOR'S DINNER

The Lord Mayor of Liverpool entertained at dinner on Saturday evening Earl Spencer, K.G., the Chancellor of the Victoria University, Lord Lister, Professor Virchow, Lord Kelvin, Sir William Turner, Sir Samuel Wilks, Sir Richard Thorne, K.C.B., Sir William Gairdner, the Vice-Chancellor of Cambridge University (Dr. A. Hill), Mr. R. B. Haldane, Q.C., M.P., Professor Michael Foster, Principal Glazebrook, the Professors of University College, and a large number of Liverpool citizens and of the invited guests of the College.

After an admirable dinner and the drinking of the usual loyal toasts, which were submitted by the Lord Mayor, Mr. R. B. HALDANE proposed the toast of "The Victoria University." This he did in the happiest and most polished manner, his text being that whereas in the olden days the tendency of university education was to make those who had received it consider that a certain aloofness from less fortunate persons was a mark of culture, now it was perceived that refinement and sterility of result did not necessarily go hand-in-hand and that a university education was no less valuable as an education because it enabled the man who had received it to be useful in the arts and commerce of his country. It was out of this spirit, Mr. Haldane said, that the movements arose which had their practical result in the Victoria University, the splendid addition to the teaching resources of which they were this day met to celebrate.

Lord SPENCER, in a short reply, testified to Mr. Haldane's knowledge of the subject by recalling the fact that the speeches of the learned Member for Haddingtonshire were some of the best made in the House on the difficult question of the reform of the London University.

The toast of "Our Visitors" was then given by Mr. EDWARD LAWRENCE and responded to in suitable terms by Professor VIRCHOW and Sir WILLIAM TURNER, the former of whom, while modestly allowing that his own labours counted for something in recent developments of pathological knowledge, took occasion to refer in terms of the warmest admiration to the life-work of his "old friend of many years—Lord Lister."

Professor MICHAEL FOSTER, in a speech which was none the less serious in intent because the speaker occasionally allowed his humorous vein to come to the surface, then proposed "University College and the Thompson-Yates Laboratories." His words had for their general motive much the same as Mr. Haldane's words. He urged all interested in the welfare of University College to leave no stone unturned to continue the work of progress, and while he reminded them that the College was still but a young institution he congratulated them upon the vigour of its growth. He pronounced the new laboratories to be the most perfect which he had ever seen and confessed that the sight of them that day had produced "a double physiological effect upon me. They took my breath away and made my mouth water." He added, amidst general applause, that whereas it was a temptation to older men to think that only in times gone by were

Digitized by Google

there giants at Liverpool, the College possessed at the present moment scientific giants in the persons of Professor Sherrington and Professor Boyce, for whose special branches of work the new laboratories were designed, while of Principal Glazebrook, who had come from Cambridge during the last few months to be Principal of University College, he said that "in Cambridge he was always setting them straight, while in Liverpool he would only have to keep them straight," a great compliment to the high level of efficiency at which the College is working.

The proceedings terminated with replies from Principal GLAZEBROOK and Professor SHERRINGTON and a unanimous vote of thanks to the Lord Mayor for his hospitality.

RECEPTION BY THE LIVERPOOL MEDICAL INSTITUTION.

The President of the Liverpool Medical Institution, Dr. Macfie Campbell, started the social proceedings in association with the inauguration of the Thompson-Yates Laboratories by inviting the guests of University College who had assembled in Liverpool to the opening meeting of the session of the institution. Dr. Macfie Campbell delivered an interesting and learned presidential address upon the older medical writers, his remarks being well illustrated by a lantern demonstration. Supper followed, and then a merry and informal smoking concert. Among the gentlemen who gave their musical assistance may be mentioned Dr. Permewan and Professor Rutherford, whose appearance on the platform was the signal for much hearty applause. Dr. David Smart gave some happy imitations of well-known teachers and professors in the Edinburgh Medical School and elsewhere—a performance which was much appreciated.

SANITARY WORK IN THE PORT OF LONDON.

THE recently issued half-yearly report of Dr. W. Collingridge, medical officer of health for the Port of London, contains much interesting information relative to the work of his department for the six months from Jan. 1st to June 30th, 1898. During that period the sanitary officers visited 15,531 vessels of all classes, 9000 of which were lying in the river and 6000 in the various docks. There were 6762 visits made to vessels arriving from abroad and 8769 to those trading coastwise, and 21 sick seamen were referred to hospital. Of the total number of visits 13,901, or 84·28 per cent., were made to British vessels, Scandinavian being next in order of frequency with 1047, or 6·74 per cent. There were 303 structural alterations for improvement of sanitary conditions, affecting 281 vessels, carried out by order of the medical officers; these alterations in 33 cases were for the purpose of improving ventilation, 23 affected the storage of water, and 247 the arrangements for lighting and heating. A firm of shipowners having complained that it was vexatious for the Port of London Sanitary Authority to call upon shipowners to alter the internal fittings of a vessel after they have been passed by the Board of Trade, it was, in reply, pointed out to the complainants that the Board of Trade is not a sanitary authority and has but very limited powers for dealing with the sanitary arrangements of a vessel, their principal interest being in its safety. The control of sanitary arrangements is the duty of a sanitary authority, and the Board of Trade has no cognisance of the cases in which sanitary arrangements either are deliberately altered or fall into disrepair. During the half year 4876 vessels arriving from abroad were visited by the medical officers. Of these 586 were medically inspected, such inspection involving the individual examination of 2733 passengers and 6135 persons forming the crews of such vessels; 47 cases of infectious disease were discovered. The cases of infectious disease dealt with in the port included 10 of small-pox, 3 of scarlet fever, 30 of enteric fever, 3 of diphtheria, and 10 of measles. One of the cases of diphtheria was landed at the Port Sanitary Hospital from a Norwegian ship on March 13th, and Mr. Hancock, the medical officer who examined and removed the case, caught the infection and had to be removed to hospital on the following day. His attack, however, was comparatively mild. There were 39 cases admitted to the hospital during the half year—namely, 7 of small-pox (with 1 death), 1 of scarlet fever, 2 of diphtheria, 18 of enteric fever (with 1 death), and 11 of other diseases. The disinfecting apparatus was in use on 62 occasions for the treatment of 4101 articles. Reference is made in the report to the smoke nuisance caused by tugs and passenger boats in the river. Where distinct negligence was manifest proceedings were taken against the owners, and in some cases convictions were obtained, but owing to differences of opinion among magistrates and to an appeal to quarter sessions considerable difficulty has been experienced by the sanitary committee in their efforts to repress the nuisance. With reference to overcrowding, a Danish ship is mentioned which arrived in London with 39 passengers all berthed in a space measuring 29ft. by 9ft. by 6ft. 9in., giving roughly 45 cubic feet of air space for each. The floor space (clear of bunks) measured 80 square feet. It being impossible to deal satisfactorily in this country with such a serious offence, the matter was brought to the notice of the Government of the country to which the vessel belonged. The articles of food condemned and destroyed during the half-year amounted to a considerable total.

CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual Calendar has just been published by the Council of the College. It shows that there are 1195 Fellows on the roll of the College (as compared with 1191 last year), 1047 of whom obtained the Fellowship by examination, 17 were elected as Members of twenty years' standing under Section 5 of Cap. 15, Vict., 129 are Fellows by election, and 2 are *ad eundem* Fellows. There are 17,199 Members (against a total of 17,333 last year) and 574 Licentiates in Midwifery—the examination for this Licence having been discontinued since 1876. The Licentiates in Dental Surgery are stated to number 1283 (an increase of 97 over last year) and the Diplomates in Public Health to number 306.

During the past collegiate year only 3 candidates presented themselves in elementary physiology, all of whom passed. 415 candidates presented themselves in elementary biology, of whom 282 passed and 133 were referred. Of 435 candidates who presented themselves in chemistry, 263 passed and 172 were referred; in materia medica, of 81 candidates, 44 passed and 37 were referred; in practical pharmacy, of 281 candidates, 207 passed and 74 were referred. The proportion of the fees paid by candidates for these examinations receivable by the College amounted to £1882 13*s.*, the examiners elected by the College receiving £210. The examiners in elementary biology are appointed by the Council of the College, those in elementary physiology in conjunction with the Royal College of Physicians of London, and those in chemistry, materia medica and practical pharmacy by the Royal College of Physicians of London under the scheme for an Examining Board in England.

The examiners in anatomy and physiology for the Second Examination are appointed in conjunction with the Royal College of Physicians of London; they have conducted the Primary Examination under the Old Regulations as well as the Second Examination of the Examining Board. 639 candidates presented themselves for examination in anatomy, of whom 345 passed and 294 were referred. 638 presented themselves in physiology, 341 of whom passed and 297 were referred. The proportion of fees paid by candidates to the College for these examinations amounted to £2889 1*s.* 6*d.*, of which the examiners received £1046 14*s.* 8*d.*

The Board of Examiners in anatomy and physiology for the diploma of Fellow, elected annually by the Council of the College, held two meetings for the examinations of 181 candidates, of whom 65 passed whilst 116 were referred. The fees paid by candidates amounted to £1181 5*s.*, of which the Board of Examiners received £724.

The Court of Examiners, 10 in number, are elected by the Council from the Fellows of the College for a period of five years. They conduct the Third or Final Examination in surgery of the Examining Board in England as well as the Second or Final Examination for the diploma of Member under the Old Regulations and the Pass or Final Examination for the diploma of Fellow. During the past collegiate year the Court held two examinations for the Fellowship and four for the Membership. At the former there were 81 candidates, 42 of whom passed; 28 were referred for six months and

Digitized by Google

11 for one year. For the Membership 781 candidates presented themselves in surgery, of whom 463 passed and 318 were referred. The fees paid by candidates for these examinations amounted to £9325 14*s.* 6*d.* and the fees paid to the Court of Examiners and the examiners in midwifery amounted to £4980 10*s.* The examiners in medicine under the scheme for an Examining Board in England are elected by the Royal College of Physicians of London. Of 709 candidates who presented themselves 464 passed and 245 were referred. The examiners in midwifery are appointed in conjunction with the Royal College of Physicians of London and have examined 893 candidates, of whom 547 passed and 346 were referred.

The Board of Examiners in dental surgery, under the Old Regulations, have held two meetings for the examination of 142 candidates, 100 of whom received the licence and 42 were referred. The fees received from candidates amounted to £1050, of which the examiners received £596 8*s.* Under the new regulations in preliminary science one examination has been held at which 2 candidates presented themselves, of whom 1 passed and 1 was referred. (This examination is identical with Part I. of the First Examination of the Examining Board in England and is conducted by the chemistry examiners appointed under the scheme.) The fees received for the examination amounted to £6 6*s.*, of which the examiners received £1 10*s.*

The examiners in public health appointed in conjunction with the Royal College of Physicians of London examined 39 candidates in Part I., 26 of whom passed and 13 were referred; in Part II., of 37 candidates 28 received their diploma and 9 were referred. The fees received by the College for both parts of the examination amounted to £180 1*s.* 6*d.* and the amount paid to the examiners to £114.

With regard to the finances of the College it appears that the income from all sources amounted to £26,613 12*s.* 5*d.*, the largest item being derived from the fees paid by candidates for the diploma of the College—viz., £16,515 1*s.* 6*d.*; the next largest being dividends on the Erasmus Wilson bequest, £4915 2*s.* 8*d.*; investments, £836 16*s.* 10*d.*; rent from chambers adjoining the College produce £750; hire of rooms, sale of questions, &c., at the Examination Hall, £683 18*s.* 2*d.*; incidental receipts at the College, £38 18*s.* 9*d.*; receipts from trust funds, £290 14*s.* 5*d.*; dividends from sinking fund for Savoy Estate, £8 2*s.* 2*d.*; fees retained for candidates, £488 5*s.*; expenses repayable by Metropolitan Asylums Board, £295 17*s.* 10*d.*; balance at Midsummer day, 1897 (including half balance of Goldsmiths' Company grant), £1790 15*s.* 1*d.*

The expenses for the year amounted to £25,406 7*s.* 9*d.*, leaving a balance at the bank and in hand at Midsummer day, 1898, of £1207 4*s.* 8*d.*, the largest item being (as in the receipts) in connexion with the examinations—viz., examiners' fees, £7673 2*s.* 8*d.*; half expenses of Examination Hall for the purposes of the examinations, £4029 3*s.* 8*d.* (this amount includes rent, rates, taxes, and insurances, which absorbs the no small amount of £2097 9*s.* 8*d.*); expenses of Fellowship and dental examinations, £400 18*s.* 1*d.*; expenses of public health examination, £36 4*s.*; half expenses of the Scientific Research Laboratories on Victoria Embankment amount to £728 19*s.* 5*d.* (this amount does not include any part of the rent, rates, taxes, insurance, fuel, or light). At the College rates, taxes, and insurance stand at £1300 6*s.* 8*d.*; extraordinary expenses—i.e., reconstructing lift to museum workrooms, College dinner, restoration of pictures, &c., £451 16*s.* 11*d*; repairs to museum, conservator's house, &c., £928 8*s.* 7*d.*; fees to members of Council, £269 17*s.*; stationery, printing, postage, &c., £380 11*s.* 4*d.*; law expenses, £393 2*s.* 11*d.*; salaries, wages, and pensions in the three departments—Museum, Library, and College, £4604 19*s.* 11*d.*; lectures, catalogues, specimens, &c., for museum, £431 10*s.* 2*d.*; purchase and binding of books, &c., for the library, £791 17*s.* 2*d.*; trust funds, £208 3*s.* 8*d.*; purchase of stock, £1293 5*s.* 5*d.*; fees returned to candidates, £294; Metropolitan Asylums Board, repayable, £240 0*s.* 2*d.*; disbursement of Goldsmiths' Research Grant, £78 8*s.*; half balance of Goldsmiths' Grant retained at the Examination Hall, £145 6*s.* 5*d.*; printing calendar, fuel, and light and miscellaneous items, £726 5*s.* 7*d.*

The Secretary's report contains an abstract of the work done by the Council and committees, the Committee of Management of the two Royal Colleges, the Research Laboratories on Victoria Embankment, also reports of meetings of Fellows and Members, elections, &c. From the annual report of the finance committee we find that the gross income of the College for the past year is £1601 less than the gross income of the previous year. As in the previous year the decrease is due to a falling off in the receipts from examinations of the combined Examining Board. Under this head there is a decrease of £50 on the first examination, of £312 on the second, of £502 on the third, and of £433 on the diploma fees paid by University candidates, a total decrease on these examinations of £1297. The amount of the receipts from examinations must not, however, be taken as an index to the number of candidates examined. There have been 65 fewer admissions to the examinations in anatomy, 61 fewer to the examination in physiology, and 42 fewer to the examination in midwifery, but there have been 24 more admissions to the examination in elementary biology, while the number of admissions to the examination in surgery is exactly the same each year. It will be seen that while the receipts on the First Examination are less the number of admissions to that examination has actually been greater. The receipts from the Fellowship examinations are £141 less and those from the dental £27 more than in the previous year. The expenditure of the College for the past year is £266 less than the previous year. The amount expended in fees to the examiners under the Combined Examining Board is only £125 less than in the previous year. As the examiners are paid a capitation fee for the number of candidates examined the small difference in the expenditure under this head for the two years shows that the large decrease in the receipts has arisen not so much from a corresponding decrease in the number of candidates as from the fact that the fees paid by them are not distributed over each year proportionately to the number of examinations for which they enter—e.g., a candidate may in one year pay the whole fee for medicine, surgery, and midwifery, being only examined in one subject that year, and may consequently in the next year be examined in the other two subjects without paying any fee. There is little difference in the expenditure at the Examination Hall and at the laboratories, that at the former being slightly less and that at the latter slightly greater than in the previous year. As regards the expenditure at the College in Lincoln's Inn-fields, there is a decrease of £45 in the special expenses of the museum and of £69 in the special expenses of the library. The expenditure on books is larger than it has been for some years, but this is more than counterbalanced by the reduction under salaries and wages. In the case of the general expenses several causes have contributed to make the total under this head an exceptionally high one. In the first place the petition of the College for exemption from payment of corporation duty has been accountable for an increase of some £360 in the law expenses of the College. Secondly, a sum of £200 has been expended upon the redecoration of the conservator's house, an outlay not likely to occur more than once in seven years. Thirdly, there has been an expenditure of £364 upon structural repairs of an extensive character to the part of the museum building abutting upon Portugal-street. In addition to these exceptional expenses the lift to the museum work-rooms has during the year been reconstructed and connected with the mains of the London Hydraulic Power Company at a cost of £260. The balance on the "income and expenditure" account amounts this year to £683, and has not been so small for some years past. It will, however, be seen that the exceptional expenses mentioned by the committee amount to £1184 and when this is borne in mind the net result of the year can hardly be considered other than satisfactory.

From the report of Dr. G. Sims Woodhead, the Director of the Research Laboratories of the two Royal Colleges, it appears that on June 3rd the number of those working or having received permission to work in the laboratories during the past year was 18.

The preparation of antitoxic serum for the treatment of cases of diphtheria in the hospitals of the Metropolitan Asylums Board has been carried out during the year and arrangements have been entered into whereby the director has been relieved of much of the routine work and much better accommodation has been obtained for the horses under treatment; so successful has the new method of preparation been that at the present time the average strength of the serum (i.e., a mixture of the sera of the horses now in use) is 375 antitoxin units per c.c.

The grant entrusted to the committee by the Goldsmiths' Company is still being administered for the furtherance of

Digitized by Google

the antitoxin treatment of diphtheria. Special apparatus for use by Dr. Brodie, Dr. Cartwright Wood, and the Director, has been purchased, and several important results have been obtained therewith. During the year special attention has been paid to the question of the standardisation of antitoxin. As a result of a careful study of the various methods which have from time to time been recommended, first in connexion with a special committee the work of which was carried out in the laboratories and then in connexion with Professor Ehrlich at the Government testing stations in Steglitz, Berlin, the Director decided to use only Ehrlich's new method, a report of which has already appeared in THE LANCET.[1] In order to facilitate the testing of anti-diphtheria serums in this country the laboratories committee authorised the Director to make arrangements for the testing of any serum sent for examination. It is satisfactory to note that two firms have availed themselves of this privilege and that all the samples of serum sent for examination have proved to be of excellent strength and quality. In fulfilment of one of the conditions of the grant from the Goldsmiths' Company that diphtheria antitoxin should, if possible, be available for use among the poorer classes of the community, antitoxic serum has been supplied to various general and children's hospitals in London during the past year, as well as to certain medical practitioners for cases fulfilling the necessary conditions. In this way 2003 doses containing 4,267,000 units have been distributed.

THE HEALTH OFFICER'S REPORT FOR THE PORT OF BOMBAY FOR 1897.

THE annual report of the Health Officer of the Port of Bombay for the year 1897, published as an appendix to the Report of the Sanitary Commissioner with the Government of Bombay for that year, shows what a vast amount of labour and care has been taken in regard to the inspection of the shipping and persons leaving that port, more especially in connexion with the epidemic prevalence of plague. To begin with, many reports have been written on the Bombay plague, but so far it has not been proved conclusively whence Bombay received the disease. Some say it was imported from China, while others affirm that it came from the slopes of the Himalayas. The acting health officer of the port, Major J. Crimmin, V.C., pertinently remarks that it seems to have escaped notice that plague is endemic in the Persian Gulf and the Red Sea coast—places much nearer home than China—and that quarantine is imposed by Egypt and Aden almost yearly against that part of the Red Sea coast between Leith and Lohaya and known as Assyr. On reference to the records it will be found that plague was epidemic in Assyr in October, 1893, July, 1894, August, 1895, and October, 1896.

The organisation for the medical inspection of all vessels and persons leaving Bombay by sea has been already described in detail in a special report by Lieutenant-Colonel MacCartie, M.B. Dub., C.I.E., in an appendix to the official account of the plague administration in the Bombay Presidency for 1897, and the acting health officer draws upon this document in his brief account of the harbour operations. As indicative of the extent of these inspections and the enormous amount of labour entailed it may be stated that the total combined results of the inward and outward inspections as well as those in the harbour show altogether that 72,752 vessels of all sorts were inspected, 1,313,117 seamen and passengers were examined and 169 cases of plague were discovered.

As regards, however, the outward inspections in connexion with plague it should be mentioned that during the earlier part of the epidemic and up to Feb. 6th, 1897, only vessels and persons bound for European and other quarantine ports were inspected. As an exodus of the plague-stricken population of the city had set in Government decided to have an examination of every vessel and native craft as well as of every crew and passenger leaving Bombay by sea for anywhere. These wholesale inspections commenced on Feb. 6th. It is, of course, impossible to gauge with any accuracy what is the exact value to be attached to any system of medical inspection as a preventative to the spread of disease. It cannot discover the disease in its incubating stage, but it can remove all suspicious cases from a vessel, and this appears to have been done. That the work was onerous enough appears from the fact that upwards of 40,000 vessels, including native craft, were inspected and a total of over 700,000 outward bound seamen and passengers were examined. The inspection had to be of a rigid and very thorough kind, the objects aimed at being the prevention of the spread of plague by sea to other Indian ports, to ports outside India, and above all to Europe, with its incalculable effects on Indian commerce.

Too much publicity cannot be claimed for the efforts made in Bombay to confine the plague within its own borders and to prevent any plague export. The description given by the Indian delegate at the Venice Convention of the searching nature of the measures followed out was received with "satisfaction mingled with incredulity"; but the description was absolutely correct, and a medical officer of the Italian Government who had been sent to Bombay to report on the measures taken there expressed, we are told, his surprise on the evidence of his own eyes at the completeness of the inspection system pursued. It may be added that in all cases where plague developed among people who had been rejected from a ship a telegram was sent to the next port of arrival warning the authorities there that a case of plague had been removed from the vessel. The two ocean-going steamers mentioned as plague-infected were the s.s. *Pekin*, which left Bombay with 1045 pilgrims for Jeddah on Dec. 28th, 1896, and the hired Government transport s.s. *Dilvara*, which left Bombay for Southampton on March 10th with 172 crew and 1063 passengers. The pilgrims in the *Pekin* had been in Bombay and living for weeks in a plague-infected locality, and all things considered it is wonderful that more cases did not occur.

No one who knows anything of the hard and monotonous and often nauseating drudgery connected with such inspections can fail to appreciate the amount and disagreeable nature of the work which fell on the medical staff and establishment of the port, and they are to be congratulated on the ability, tact, and success with which it was performed. We are compelled to pass over a great portion of Major Crimmin's narrative and details. It must suffice to say that, in our opinion, it is an excellent and interesting document.

MEDICAL UNION IN EAST LONDON.

THE East Suburban Medical Protection Society, Limited, have held their first general meeting since the registration and legal constitution of this newly formed medical union. The members assembled at the West Ham Hospital on Oct. 6th and included representatives from Leytonstone, West am, Tidal Basin, Romford-road, Walthamstow, Stepney, Ilford, Forest Gate, Barking-road, Leyton, Custom House, Plaistow, Romford, Dalston, Bow, &c.

The President, Dr. Frederick Smith, senior assistant physician at the London Hospital, occupied the chair. After the minutes of the first statutory meeting had been read and confirmed the quarterly report of the Executive Council was presented. It showed that four council meetings had been held during the quarter and that the scheme for debt collecting had been practically applied to the material benefit of several members of the society. In regard to the Plaistow Maternity Home, the position of the society in relation with this institution had been the subject of a carefully-prepared report which showed that the organised members of the profession proposed two reforms. First, the abolition of all maternity fees, and, secondly, that the medical profession should be adequately represented upon the governing body of the maternity. It was further explained that solicitors and standing counsel had been appointed to act for the society in all matters for which legal aid and advice were required. The chairman commented at length on this report and together with the treasurer's report it was unanimously approved by the meeting. The chairman then referred in grateful terms to the aid the society had obtained from THE LANCET and spoke in complimentary terms of the energy

and enterprise shown in the endeavour to collect in all parts of the country useful evidence as to the position of the medical profession.

THE MEDICAL SCHOOLS.

London Hospital.—The annual dinner of the old students of the London Hospital was held at the Medical College Library on Monday evening last, when there was a large attendance under the chairmanship of Mr. C. W. Mansell Moullin. After the usual toasts Mr. Moullin proposed the health of the London Hospital and its medical school, and in a few eloquent words spoke of the great improvements which are being at the present time carried out at this great institution of the East-end. On behalf of the House Committee of the hospital Mr. W. Douro Hoare (chairman of the College Board) replied and explained to those assembled that the first work to be undertaken would be the rebuilding of the operating theatres and the rearrangement of the two wards in the centre block. This work will be begun as soon as ever the temporary wards for 96 beds—which are being erected in the garden—are completed. Plans for these new theatres have been most carefully developed, and as no expense will be spared the most perfect arrangement of theatres possible is aimed at. Mr. Hoare concluded with a few cordial remarks on the pleasant relations existing between the House Committee and the medical staff of the London Hospital. On behalf of the medical staff Dr. Stephen Mackenzie (senior physician) replied and expressed the obligation under which the staff considered themselves to be to the governors of the hospital for the great liberality with which it had been decided to improve the hospital and to give scope for the teaching for which there is such abundant and excellent clinical material. Dr. Sansom proposed the health of the chairman, who suitably replied. Amongst those who were present were Mr. Carr-Gomm (a former chairman of the House Committee), Mr. Brudenell Carter, Mr. Hurry Fenwick, Dr. Herman, and other members of the staff and of the House Committee.

St. Bartholomew's Hospital and College.—The entrance scholarships have been awarded as follows:—Junior Scholarship in Chemistry, Physics, and Biology (value £150): C. C. Robinson and J. Burfield (equal). Senior Scholarship in Biology and Physiology (value £75): L. J. Picton. Preliminary Scientific Exhibition in Chemistry, Physics, and Biology (value £50): H. F. Forster. Jeaffreson Exhibition in Latin, Mathematics, &c.: T. Jefferson Faulder. Shuter Scholarship in Anatomy, Physiology, and Pharmaceutical Chemistry (value £50): F. C. Shrubsall.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Durham County Sanitary District.—Dr. Eustace Hill has now the satisfaction of being able to report that all the sanitary authorities throughout the county have adopted the Infectious Diseases Notification Act and we congratulate him on the success of his efforts. The estimated population of the county at the middle of 1897 was 786,400 and the general death-rate was 16·8 per 1000. The death-rate for the six boroughs was, it is of interest to note, considerably lower than that of the other urban districts in the county. There was a marked decrease on former years in the death-rate from zymotic diseases, and certainly one of the most hopeful signs for the future is the fact that there has been a considerable reduction in the mortality from enteric fever. Durham, as our readers are probably aware, has for many years enjoyed an unenviable notoriety for its enteric fever death-rate. Dr. Hill regards the decrease recorded as in the main due to the abolition of a large number of privy middens and the carrying out of other improvements making for the purification of polluted soil. The only isolation hospital erected in the county during 1897 was a "temporary" iron structure, but the Local Government Board constituted a joint hospital board, and in other instances sites have been procured. Important progress was made during the year in the matter of water-supply and purification in certain parts of the county, and much improvement was effected in the housing of the working-class population. But little was done in 1897 towards the prevention of river pollution, and Dr. Hill hopes that, as a result of the present Commission on Sewage Disposal Methods, the Local Government Board will be able to dispense with the use of land in cases where biological methods are to be carried out. With regard to dairies, cowsheds, and milkshops Dr. Hill reports that absolutely no precautions are taken in the county to guard against the consumption of milk from tuberculous cows, and he trusts, as do we all, that the recommendations of the recent Royal Commission on the subject will soon be embodied in a Government Bill. The inspection of factories and workshops seems to be a dead letter in the county of Durham, but in the direction of new by-laws there has of late been much activity manifest.

Essex County District.—The population of this county is increasing very rapidly and it was estimated to the middle of 1897 at close upon 700,000. Dr. Thresh thinks that at the next census Essex may be found to have developed at a greater rate than any other county in the country. Much attention was given during 1897 to the important question of water-supply in the several districts of the county, chemical and bacteriological examinations being made more frequently than heretofore. We are glad to see, too, that in their zeal to have the water tested many of the sanitary authorities have not overlooked the necessity of examining the areas or localities from which the supplies are derived. Dr. Thresh is evidently getting somewhat anxious as to the future water-supply of the county. The London clay, which in most parts of the county overlies the chalk, is, Dr. Thresh tells us, being pierced in all directions by deep wells, and he anticipates that this will soon result in a considerable and permanent lowering of the water level. When this is brought about there is danger, he thinks, that the character of the deep well water hereabouts may be materially altered by its being impregnated with sea water through the agency of the outcrops of chalk under the Thames and perhaps in the German Ocean. The water at present yielded by the deep wells varies materially in character in different parts of the county. On the north, towards the outcrop, it is hard and a characteristic chalk water. As, however, the distance from the outcrop increases the water becomes soft and contains much salt and carbonate of soda. Near the coast and tidal river some of the deep wells yield brackish water. Dr. Thresh is carefully pursuing this interesting subject by making analyses of water from the chalk wells in the county and collecting sections showing the thickness of the overlying ground and London clay in the several parts of the county.

St. Pancras Sanitary District.—Dr. J. F. J. Sykes discusses in his annual report for 1897 the question as to whether or not patients suffering from diphtheria and enteric fever should be admitted into the general hospitals—a practice which still obtains in some London hospitals. With regard to diphtheria there is certainly, as Dr. Sykes remarks, a decided objection to treating cases of this disease in the general wards of a general hospital and, assuming that such cases are admitted at all, they should be treated in special isolation wards. As to enteric fever, however, Dr. Sykes thinks that there is a "considerable amount of leading opinion that cases of this disease should be treated in the general wards of a general hospital." We should hardly be prepared to go all the way with Dr. Sykes in this last statement, although there are certainly still many who believe that enteric fever may be treated without danger to other patients suffering from a different disease. Whatever may be the correct method of expressing the state of feeling existing upon this subject we must express our agreement with Dr. Sykes that the treatment of enteric fever side by side with cases of other diseases is, to say the least of it, undesirable, and this is much more the case when the same nurse attends enteric fever patients and others at the same time. Certainly, if this practice is carried on the importance of rigid regulations and of the strict enforcement thereof cannot, as Dr. Sykes observes, be too much insisted upon.

The Isle of Wight Rural District.—The most pressing necessity—in a sanitary sense—of this district, one of considerable area and of no little sanitary importance to the

Digitized by Google

large number of visitors who annually visit it, is isolation accommodation. We wonder if visitors thoroughly comprehend that in the greater part of this island there is no proper isolation provision wherein to isolate a case of scarlet fever or diphtheria which may perchance occur in a house or hotel in which they may be lodging. The rural district council are said by Dr. Joseph Groves, in his very complete report on this district, to have for the last twelve years regarded the provision of a hospital as a sanitary necessity, but, as far as we are able to gather, the efforts which they have made to carry into effect their conscientious scruples would seem to have been of a somewhat lukewarm nature. It is by no means clear that they are not glad to be possessed of some excuse to leave things in their present unsatisfactory state, and their medical officer of health may understand the neutral attitude of the members when he remarks, "After the expenditure of infinite labour and time through a long series of years you have declined as a sanitary authority solemnly charged with serious obligations to advance in this matter along the path of progress upon which you have entered." Clearly this district council prefer to waste time rather than to make a judicious investment; but we trust the time is coming when visitors before they take their children to a health resort, be it an urban or a rural one, will ascertain beforehand what manner of isolation accommodation exists in the locality.

Berkshire Combined Sanitary District.—Dr. W. T. G. Woodford in reporting upon this large area, which embraces 17 sanitary districts, has been at pains to contrast the mortality for the five years 1893–97 from the chief zymotic diseases, notifiable and non-notifiable, as illustrated by the 15 districts accepting notification, and the 2 districts, Maidenhead and Newbury urban, which reject it. The results are at least very suggestive. For the period in question the mean yearly death-rates from the chief zymotic diseases and from erysipelas were for the notifying districts 9·96 per 10,000, as against 22·22 per 10,000 for the non-notifying districts. It is true that the comparison is between 2 urban districts on the one side as against 13 rural and 2 urban districts on the other. But Dr. Woodford states that the general sanitary condition of the non-notifying districts is not below that of the rest of the combined district and he is inclined to regard the discrepancy as due to the control exercised over infectious diseases in the one case and the absence of such control in the other. The fact, too, that the difference is much more marked in the case of notifiable diseases than in non-notifiable diseases is in support of this view.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6532 births and 4408 deaths were registered during the week ending Oct. 8th. The annual rate of mortality in these towns, which had declined from 24·6 to 21·8 per 1000 in the four preceding weeks, further fell last week to 20·5. In London the rate was 18·8 per 1000, while it averaged 21·7 in the thirty-two provincial towns. The lowest rates in these towns were 12·2 in Croydon, 12·6 in Cardiff, 14·9 in Brighton, and 15·6 in Portsmouth; the highest rates were 27·5 in Norwich, 27·6 in Salford, 29·0 in Liverpool, and 30·4 in Sunderland. The 4408 deaths included 774 which were referred to the principal zymotic diseases, against 1455 and 1118 in the two preceding weeks; of these, 530 resulted from diarrhœa, 70 from diphtheria, 65 from "fever" (principally enteric), 43 from whooping-cough, 41 from measles, and 25 from scarlet fever. The lowest death-rates from these diseases were recorded in Brighton, Derby, Birkenhead, and Halifax; while they caused the highest rates in Norwich, Swansea, Sunderland, and Gateshead. The greatest mortality from measles occurred in Norwich and Gateshead; from "fever" in Leeds, Newcastle-upon-Tyne, and Sunderland; and from diarrhœa in Blackburn, Salford, Burnley, Sunderland, Hull, Gateshead, and Norwich. The mortality from scarlet fever and from whooping-cough showed no marked excess in any of the large towns. The 70 deaths from diphtheria included 34 in London, 5 in West Ham, 5 in Swansea, 4 in Leeds, 4 in Sheffield, 3 in Portsmouth, 3 in Birmingham, and 3 in Leicester. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital was 2606 on Saturday last, the 8th inst. against 2319, 2353, and 2459 at the end of the three preceding weeks; 358 new cases were admitted during the week, against 242, 288, and 300 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 157 and 200 in the two preceding weeks, further rose to 226 last week, and were 7 above the corrected average. The causes of 42, or 1·0 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Salford, Bradford, Hull, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·7 and 19·1 per 1000 in the two preceding weeks, rose again to 20·6 during the week ending Oct. 8th, and slightly exceeded the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18·7 in Perth and 19·6 in Aberdeen and in Greenock to 22·7 in Paisley and 24·3 in Dundee. The 621 deaths in these towns included 62 which were referred to diarrhœa, 19 to whooping-cough, 14 to scarlet fever, 14 to "fever," 7 to diphtheria, and 7 to measles. In all, 123 deaths resulted from these principal zymotic diseases, against 156 and 127 in the two preceding weeks. These 123 deaths were equal to an annual rate of 4·1 per 1000, which was 0·5 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had declined from 110 to 75 in the three preceding weeks, further fell to 62 last week, of which 22 occurred in Glasgow, 16 in Dundee, and 9 in Edinburgh. The 19 deaths from whooping-cough exceeded by 2 the number in the preceding week, and included 10 in Glasgow and 6 in Edinburgh. The fatal cases of scarlet fever, which had been 3, 6, and 11 in the three preceding weeks, further rose to 14 last week, of which 9 occurred in Glasgow, 2 in Dundee, and 2 in Aberdeen. The 14 deaths referred to different forms of "fever" corresponded with the number recorded in the preceding week, and included 10 in Glasgow and 4 in Paisley. Of the 7 fatal cases of diphtheria 4 occurred in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 85 and 87 in the two preceding weeks, further rose to 105 last week, but were 57 below the number in the corresponding period of last year. The causes of 23, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the four preceding weeks from 30·7 to 24·6 per 1000, further fell to 23·1 during the week ending Oct. 8th. During the thirteen weeks of last quarter the death-rate in the city averaged 23·1 per 1000, the rate during the same period being 19·4 in London and 18·7 in Edinburgh. The 155 deaths registered in Dublin during the week under notice showed a decline of 10 from the number in the preceding week, and included 19 which were referred to the principal zymotic diseases, against 32 and 38 in the two preceding weeks; of these, 14 resulted from diarrhœa, 3 from whooping-cough, 2 from "fever," and not one either from small-pox, measles, scarlet-fever, or diphtheria. These 19 deaths were equal to an annual rate of 2·8 per 1000, the zymotic death-rate during the same period being 2·4 in London and 2·8 in Edinburgh. The deaths from diarrhœa, which had been 20 and 27 in the two preceding weeks, declined again to 14 last week. The 3 fatal cases of whooping-cough were below the number recorded in any recent week. The deaths referred to different forms of "fever," which had been 6 and 5 in the two preceding weeks, further declined to 2 last week. The 155 deaths in Dublin last week included 46 of infants under one year of age and 34 of persons aged upwards of sixty years;

the deaths of infants showed a slight increase, while those of elderly persons showed a decline from the number in the preceding week. Six inquest cases and 3 deaths from violence were registered; and 40, or more than a fourth, of the deaths occurred in public institutions. The causes of 10, or more than 6 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1898.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during September in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis last month it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·9 per 1000 of the population, estimated at 4,504,766 persons in the middle of this year. In the three preceding months the rates had been 7·1, 8·1, and 6·5 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in St. George Hanover-square, St. James Westminster, St. Martin-in-the-Fields, City of London, St. George-in-the-East, Rotherhithe, and Lewisham; while they showed the largest excess in Stoke Newington, Holborn, St. Luke, Mile End Old Town, St. George Southwark, Newington, and Bermondsey. Two cases of small-pox were notified in London during September, against 6, 2, and 5 in the three preceding months; of these, 1 occurred in Whitechapel and 1 in Wandsworth sanitary areas. One case of small-pox was admitted into the Metropolitan Asylum Hospitals during September, but none remained under treatment at the end of the month. The prevalence of scarlet fever in London showed a marked increase upon that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Stoke Newington, Hackney, St. Saviour Southwark, St. George Southwark, Newington, St. Olave Southwark, Bermondsey, Woolwich, and Plumstead. The Metropolitan Asylum Hospitals contained 2425 scarlet fever patients at the end of September, against 2146, 2255, and 2207 at the end of the three preceding months; the weekly admissions averaged 270, against 208, 242, and 202 in the three preceding months. The prevalence of diphtheria in London during September showed a considerable increase upon that recorded in the preceding month; this disease was proportionally most prevalent in Holborn, St. Luke, Mile End Old Town, St. George Southwark, Newington, Battersea, and Lee sanitary areas. There were 1024 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of September, against 971, 1014, and 865 at the end of the three preceding months; the weekly admissions averaged 163, against 134, 146, and 107 in the three preceding months. The prevalence of enteric fever in London showed a further increase upon that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Westminster, Hackney, Shoreditch, Poplar, Newington, and Greenwich. The Metropolitan Asylum Hospitals contained 155 enteric fever patients at the end of September, against 53, 87, and 118 at the end of the three preceding months; the weekly admissions averaged 28, against 11, 16, and 21 in the three preceding months. Erysipelas was proportionally most prevalent in St. Giles, Bethnal Green, Whitechapel, Limehouse, and Mile End Old Town sanitary areas. The 11 cases of puerperal fever notified in London during September included 2 in Camberwell sanitary area.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, Oct. 1st, the deaths of 7249 persons belonging to London were registered, equal to an annual rate of 21·0 per 1000, against 14·6, 14·7, and 20·7 in the three preceding months. The lowest death-rates in the various sanitary areas were 12·2 in Hampstead, 12·6 in St. Martin-in-the-Fields, 12·8 in St. George Hanover-square, 14·3 in Stoke Newington, 14·8 in Kensington and in Lee, and 15·0 in St. Olave Southwark; the highest rates were 26·7 in Woolwich, 26·9 in Limehouse, 27·3 in Shoreditch, 28·6 in Holborn, 29·2 in St. Saviour Southwark, 30·5 in St. George-in-the-East, and 30·8 in St. George Southwark. During the four weeks of September 1778 deaths were referred to the principal zymotic diseases in London; of these, 46 resulted from measles, 30 from scarlet fever, 120 from diphtheria, 125 from whooping-cough, 40 from enteric fever, 1417 from diarrhœa, and not one death from small-pox, typhus, or any ill-defined form of continued fever. These 1778 deaths were equal to an annual rate of 5·1 per 1000; among the various sanitary areas the lowest zymotic death-rates were recorded in St. George Hanover-square, St. James Westminster, Hampstead, St. Martin-in-the-Fields, City of London, and Rotherhithe; and the highest rates in Clerkenwell, Limehouse, Mile End Old Town, St. Saviour Southwark, St. George Southwark, Greenwich, and Woolwich. The 46 fatal cases of measles were 33 below the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Bethnal Green and Whitechapel sanitary areas. The 30 deaths referred to scarlet fever were less than half the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Chelsea and Bermondsey. The 120 fatal cases of diphtheria were 58 below the corrected average number; this disease showed the highest proportional fatality in Holborn, Clerkenwell, Mile End Old Town, Poplar, Newington, Bermondsey, and Battersea sanitary areas. The 125 deaths from whooping-cough slightly exceeded the corrected average number; among the various sanitary areas this disease was proportionally most fatal in St. George-in-the-East, Newington, Lewisham, and Woolwich. The 40 fatal cases of enteric fever were 21 below the corrected average number; this disease showed the highest proportional fatality in Clerkenwell, Shoreditch, and Greenwich sanitary areas. The 1417 deaths referred to diarrhœa were as many as 1062 above the corrected average number; this disease was proportionally most fatal in Clerkenwell, Shoreditch, Limehouse, St. Saviour Southwark, St. George Southwark, Greenwich, and Woolwich sanitary areas. In conclusion, it may be stated that the aggregate mortality in London last month from these principal zymotic diseases was just double the corrected average, owing to the excessive fatality of summer diarrhœa.

Infant mortality in London, measured by the proportion of deaths of children under one year of age to registered births, was equal to 303 per 1000, which, owing to the continued prevalence of summer diarrhœa, very considerably exceeded the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, St. James Westminster, Marylebone, Stoke Newington, St. Luke, and St. Olave Southwark; and the highest rates in Hammersmith, St. Martin-in-the-fields, Clerkenwell, Shoreditch, St. Saviour Southwark, St. George Southwark, and Greenwich.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced: — Staff Surgeons: William Spry to the *Impregnable;* J. W. Slaughter to the *Cleopatra;* and William Tait to the *Mars.* Surgeon Alfred H. L. Cox to the *Cambridge.*

ROYAL ARMY MEDICAL CORPS.

The following gentlemen have been nominated for entrance to the Army Medical School at Netley as surgeons on probation from the Royal Army Medical Corps:—F. Ashe, Owens College, Manchester; H. E. Haynes, St. Thomas's; L. Humphrey, Guy's Hospital; G. J. A. Ormsby, Dublin University; H. D. Packer, Guy's Hospital; H. K. Palmer, St. Bartholomew's; R. S. Rodger, Edinburgh University; N. J. C. Rutherford, Trinity College, Dublin; A. O. B. Wroughton, St. Bartholomew's; Mr. T. J. Jordan and Mr. W. W. Scarlett, Royal College of Surgeons in Ireland.

Surgeon-General John B. Hamilton is placed on retired pay. Colonel William D. Wilson to be Surgeon-General, vice J. B. Hamilton. Lieutenant-Colonel Alexander Anderson is placed on retired pay.

Major L. Haywood has joined at Mullingar for duty. Major J. C. Culling is posted to the Station Hospital, Western Heights, for duty. Lieutenant-Colonel A. Kirwan, retired pay, A.M.S., is appointed to the medical charge of the Leicestershire Regimental District. Lieutenant-Colonel

Digitized by Google

R. Exham is appointed Principal Medical Officer Western District, vice Surgeon-General J. B. Hamilton, retired. Surgeon-General W. Taylor, late P.M.O. of the Khartoum expedition, will succeed Surgeon-General A. A. Gore as P.M.O. of the British Forces at Army Headquarters in India.

INDIA AND THE INDIAN MEDICAL SERVICES.

Lieutenant-Colonel Carr-Calthrop, Bengal Establishment, is granted the temporary rank of Colonel while officiating as Principal Medical Officer and Sanitary Commissioner, Assam, vice Colonel A. Stephen, appointed officiating Inspector-General, Civil Hospitals, Punjab. The services of Major Bannerman (Madras) are replaced at the disposal of the Government of Madras.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain E. W. St. V. Ryan to be Surgeon-Major.

VOLUNTEER CORPS.

Artillery: 2nd East Riding of Yorkshire (Western Division, Royal Artillery): Thomas Cameron to be Surgeon-Lieutenant.

THE LATE SPANISH-AMERICAN WAR.

The indictment which "an eye-witness" brings against the Washington War Office authorities in his second article in the *Saturday Review* of Oct. 8th is anything but pleasant reading. If all which he has to say regarding the sufferings of the sick and wounded at Santiago, owing to the want of medical attendance in Cuba, the absence of any prompt aid to the wounded, the insufficiency and distance of the hospital accommodation and the inadequacy of the hospital stores and supplies be correct, there must have been grave mismanagement somewhere on the part of those responsible for the medical service. We must now, however, await the result of the official inquiry into the subject. Making every allowance for the state of unpreparedness which existed, the mixed nature of the force—composed, however, as it certainly was, of fine fighting material—and the hurried nature of the expedition altogether, there still seems to have been a lamentable want of administrative and organising capacity. That war was almost certain must have been foreseen, and the nature of the service, the climate, and the topographical features and diseases of the country were known, therefore the want of any proper provision seems inexplicable under the circumstances. It is to be feared that political considerations had too much influence and led to jobbery on the part of contractors and to wrong appointments being made. At any rate, a writer in *Scribner's Magazine* for this month does not hesitate to attack General Shafter's conduct and generalship during the San Juan campaign. In another column will be found an extract from an editorial article in the *Philadelphia Polyclinic* supporting the Medical Corps of the United States army.

We notice in a telegram from Manila of Oct. 8th that there has been a small but sharp outbreak of small-pox among the American troops there, 14 cases and 6 deaths having been returned in the course of a few days. That scourge of all modern armies on field service, typhoid fever, is also prevailing, 8 deaths therefrom having been reported.

THE LATE CAMPAIGN IN THE SOUDAN.

As might have been confidently expected, and was indeed foreseen, the troops returning from the Soudan to Lower Egypt and elsewhere have begun to harvest the results of the sickness sown and contracted during their late campaign. The medical service may, however, fairly congratulate itself on the favourable results, for the loss of life from sickness has so far been much less than might have been expected; still, it always happens, as we have already said, that sickness and mortality follow in the wake of a campaign like that lately conducted on the Upper Nile. There have been a number of cases of enteric fever among the British troops returning from Atbara and Omdurman, some of which have been fatal, but the number of these has been much exaggerated. If we may judge from the appearance of those officers and men we have seen, the heat-exposure, strain, and fatigue have told upon them, for they look what is termed rather "drawn." Colonel Young, Commissioner of the National Aid Society, in addition to the aid which the society has afforded in the way of Nile transport for the sick and wounded, has presented the Sirdar with £300 for the benefit of the sick and wounded among the Egyptian soldiers engaged in the Soudan campaign, and a further sum of £200 for the purchase of articles urgently needed for the treatment of the Dervish wounded now under medical treatment at Omdurman.

THE INDIAN MEDICAL SERVICE.

The annual medical service dinner took place at the United Service Club, Simla, on Sept. 19th, Surgeon-General Harvey, C.B., D.S.O., presiding. The President made an excellent as well as a sensible and inspiriting speech in proposing prosperity to the service. During the last four years the Indian Medical Service had been severely tried by the exigencies of famine, plague, and war, but the service always rose to its duty and was always true to itself. There was no evidence of decadence—quite the contrary. In the frontier operations an immense amount of admirable work was done. The names of Young, Hugo, Fisher, and Selby, said the chairman, might well be bracketed with those of Crimmin and Whitchurch. In addition to those who had distinguished themselves at the front many officers had struggled with plague and famine and some of them had lost their lives in doing their duty. We may add that the Royal Warrant conferring the new titles on officers of the Indian Medical Service has reached Simla although not yet officially published.

DEATHS IN THE SERVICES.

Staff Surgeon Octavius Stephens Fisher, R.N., at South Queensferry, N.B., in his thirty-sixth year. He was appointed Surgeon in the Navy in 1885, and promoted Staff Surgeon in 1897.

Colonel Randolph Caldecott, I.M.S., Bombay, on Sept. 29th, aged fifty-one years. He entered the service in 1869, was promoted Surgeon in 1873, Surgeon-Major in 1891, Surgeon-Major (ranking as Lieutenant-Colonel) in 1889, Brigade-Surgeon in 1895, and Surgeon-Colonel in 1897.

The *Pioneer Mail* for Sept. 23rd has the following items of intelligence regarding the movements of officers in the Medical Services serving in India:—Brigade-Surgeon-Lieutenant-Colonel J. Young, Indian Medical Service, has been appointed Principal Medical Officer, Malakand Field Force, *vice* Brigade-Surgeon-Lieutenant-Colonel W. J. Charlton. Surgeon-Colonel W. P. Warburton, Inspector-General of Civil Hospitals, North-West Provinces and Oudh, goes on furlough. Surgeon-Colonel Hall, Inspector-General of Jails, will officiate, and Surgeon-Major MacTaggart will act as Inspector-General of Jails. Brigade-Surgeon-Lieutenant-Colonel J. Moran, I.M.S., retires from the service this month (October). Lieutenant-Colonel A. Anderson, R.A.M.C., officiates as Principal Medical Officer, Secunderabad district, vice Colonel Major, who proceeds home on sick leave.

The Queen has granted unto the under-mentioned officers Her Majesty's Royal licence and authority to wear the Insignia of the following Orders conferred upon them by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan of Turkey: Captain Richard Hugh Penton, D.S.O., Royal Army Medical Corps, Osmanieh (Fourth Class); Captain Philip Henry Whiston, Royal Army Medical Corps, Medjidieh (Fourth Class).

DIPHTHERIA IN LONDON.—In the week ended on Oct. 1st the registered deaths from diphtheria in London were 33, as against 30, 29, and 29 in the three weeks preceding, but were 22 below the corrected decennial average for the corresponding weeks of the ten years 1888–97. Bermondsey, Hackney, and Wandsworth sanitary areas were respectively credited with 4 deaths, while Poplar and Battersea had each 3 deaths. The admissions of diphtheria cases to hospital in the week numbered 197, as compared with 148, 158, and 155 in the preceding three weeks. In all 33 fatalities the age was under twenty years, 23 being of children under five years of age. In the Outer Circle 17 deaths from the disease were registered, of which 7 belonged to West Ham registration district. Last week the registered deaths from diphtheria in London rose to 34, but were still 18 below the corrected decennial average. 4 belonged to Islington and 3 each to Limehouse and Wandsworth sanitary areas. All were of persons aged under twenty years. The fresh cases admitted to hospital during the week numbered 180. In the Outer Circle the registered diphtheria deaths fell to 10, of which 6 belonged to West Ham registration district.

MEDICAL CHARITIES.

To the Editors of THE LANCET.

SIRS,—The series of lectures arranged for the next two months by the Joint Lectures Committee of the Charity Organisation Society will, I believe, be of interest to members of the medical profession and their friends. I venture, therefore, to send you a note about them. They are eight in number and will be delivered at the Portman Rooms, Baker-street, at 4.30 P.M. on Fridays, beginning on the 21st inst., when Sir William Broadbent has kindly consented to preside and give a short introductory address. The lectures are on the following subjects: The Growth of Medical Charities (Oct. 21st), Mr. C. S. Loch; the Dispensary (Oct. 28th), Dr. L. A. Hawkes; the Hospital (Nov. 4th), Mr. Clinton Dent; the Poor-law Infirmary (Nov. 11th), Dr. T. D. Savill; the Lunatic Asylum (Nov. 18th), Dr. Rayner; District Nursing (Nov. 25th), Miss Amy Hughes; Sick Insurance (Dec. 2nd), Mr. F. G. P. Neison; and the Provident Dispensary and District Nursing (Dec. 9th), Dr. J. B. Hurry.

Mrs. Hill, the hon. secretary, 19, Park-mansions, Battersea-park, S.W., will gladly send prospectuses to all inquirers.

I am, Sirs, your obedient servant,

C. S. LOCH,
Secretary, Charity Organisation Society.

Buckingham-street, Strand, W.C., Oct. 12th, 1898.

THE CONSCIENTIOUS OBJECTOR.

To the Editors of THE LANCET.

SIRS,—The extraordinary legislation of the past session in the matter of vaccination—which has made us the laughing-stock of all other civilised nations in consequence of the surrender by Parliament of scientific truth to the prejudices of the ignorant—has compelled me to be a "conscientious objector" in the opposite sense to the one created by the recent Acts of Parliament. I have the honour to be a magistrate as well as a physician and I have, after very careful consideration, determined that (knowing what I do) I cannot conscientiously sign a certificate of exemption from compulsory vaccination except in a case of proved bad health. I have therefore determined to retire from the bench whenever an application comes before me for such a certificate. I venture to hope that my medical brethren who are magistrates will see their way to pursue the same line of action. I am, Sirs, yours faithfully,

THOS. W. THURSFIELD, M.D. Aberd., F.R.C.P. Lond.,
J.P. for the County of Warwick.

Leamington, Oct. 8th, 1898.

THE EXCLUSION OF INFECTION FROM SCHOOLS.

To the Editors of THE LANCET.

SIRS,—Will you be good enough to give publicity to the following facts, which I think should be widely known in the interests of parents and schools?

I have a preparatory school for boys and for some years I made use of the following certificate which I asked parents to fill up before the beginning of each term, and this was regularly done.

CERTIFICATE.

"I certify that ..... is quite fit to return to school, that he has not had any infectious illness during the holidays, neither has he to the best of my knowledge been exposed to any danger of infection during the three weeks preceding his return to school."

During these years measles (twice), chicken-pox, and whooping-cough were introduced into the school and could all be traced unmistakeably to the holidays in spite of this certificate, and as a climax a boy returned with scarlatina in its very mildest form but with throat slightly ulcerated and a faint rash. The consequences were disastrous to me, resulting in no less than 15 cases and involving me in a pecuniary loss of over £500, besides all the inconvenience and loss to parents caused by illness leading to breaking-up of the school. I have now obtained the almost unanimous consent of the parents to a still more stringent precaution. I require a medical examination and certificate dating not later than *the day previous* to the boy's return to school. The certificate appended to the one quoted above reads thus:—

"I certify that I have this day carefully examined ..... who returns to school to-morrow, and that there are no signs of any infectious complaint about him." (Signature of medical man.) .....

In addition to this I get my own school medical attendant to see all the boys immediately on their arrival at school.

On Sept. 30th, a Friday, my boys came back to school; 21 of us travelled together in a saloon from London. On our arrival my medical man found that one boy admitted having some spots on his body; he examined him and found well-developed chicken-pox, some of the spots being obviously about a week old. The boy knew he had been having "heat-spots" for some time. The medical man at home saw him on the Thursday, after which he was poorly and his temperature rose to 100·1° F., so the medical man was sent for to see him again the same evening and again on Friday to satisfy the mother that he was fit for school. I hold the medical man's certificate worded exactly as above. Chicken-pox being what it is and the boy having been for over an hour in the train with so many others I fully expect that every boy in the school who has not previously had the illness will have it now and all their parents and the school must suffer accordingly.

But this is not all. Finding that this particular boy said the medical man had not examined his body at all on the Thursday I pushed my inquiries further, with the following results. Out of 32 boys whose certificates I hold only 14 had been examined on their chest, 17 in the throat, several had simply been told to put their tongues out, 5 had not been examined at all as to either tongue, throat, or chest, and none at all were examined on the head. The net result is that out of the 23 medical men from various parts of England and Scotland only 7 (including 2 distinguished London practitioners) made a thorough examination before signing this explicit declaration, "I have carefully examined." Such a cursory examination as satisfied most of these gentlemen would have failed to discover the case of scarlatina referred to above quite as surely as it failed to discover the chicken-pox on the present occasion.

My object in writing to you, Sirs, is to ask your assistance in bringing this matter before the medical profession, who are in so many ways the best friends of schoolmasters, whose sympathetic help is so necessary to us, and with whom we wish to work in complete harmony. But my recent experience seems to show that many scarcely quite realise yet the importance of safeguarding schools from epidemics or the ease with which the first symptoms of infection may escape even the professional eye. For obvious reasons I can only sign myself, Sirs,

Yours faithfully,

Oct. 3rd, 1898. A PREPARATORY SCHOOLMASTER.

P.S.—It is only fair to the medical man mentioned above to say that just before posting this I have received a letter from him saying that he examined the boy's lungs both back and front on the Thursday and there were no chicken-pox marks upon him then. He intimates that the spots were only "a pustular eruption."

"ULCERATING GRANULOMA OF THE PUDENDA."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 9th last attention is drawn to the disease termed "ulcerating granuloma of the pudenda" which appears to be prevalent in the West Indies. There is no doubt that the disease is similar to anaffection which is prevalent in India, a description of which was given by myself in the *Indian Medical Gazette* of May, 1898, under the term "chronic venereal sores." In India it is believed that the disease is venereal in origin—the ulceration originating as a chancre or bubo—although not syphilis. The disease is of a most inveterate character and very difficult to cure. I am, Sirs, yours faithfully,

J. MAITLAND,
Lieutenant-Colonel, I.M.S

General Hospital, Madras, Sept. 19th, 1898.

LYMPH-GLAND JUICE IN THE TREATMENT OF CANCER.

To the Editors of THE LANCET.

SIRS,—Will you permit me to indicate a new principle in the treatment of malignant disease which may afford important results? The nuclear particles of epithelioma are, as everyone knows, carried by the lymph to the adjoining glands, which arrest them and so prevent a general blood-contamination. Individual examples of this lesion (which only retrogressive pathology would confuse with carcinoma) manifest a remarkable difference in the speed with which these glands are infected. Thus ordinary "cancer of the tongue" establishes active growth within the glands in six weeks, often less; whereas epithelial lesions on the foot or hand set up no secondary gland metastases for at least several months, and those on the external genitals hardly for a year. A mammary carcinoma beginning close to the axilla involves gland enlargement almost simultaneously. One arising at the sternal border does not implicate those organs for eight or ten weeks later.

Turning to another cancer variety, true sarcoma, we find that the lymph glands are never distally infected at all, although many of the cases are remarkably virulent, and it is impossible to doubt that nuclear fragments are carried to them in large numbers. There is no gland deposit with a sarcoma unless either by direct infiltration or concurrently with general blood contamination. The case cited at p. 87 of my "Recurrence of Cancer" proved that there had been irritation of the lymph glands sufficient to induce enlargement and greatly to modify structure, yet without the survival of any malignant protoplasm. I am therefore impelled to the conclusion that it is the function of the lymph-glands, not only to arrest, *but actually to destroy*, the protoplasm of cancer. In the ordinary course of events this takes place only up to a certain point. Eventually the gland is overpowered by stress of numbers. But under some circumstances, as above indicated, the resistance is long-continued and the number of infective particles killed must be considerable.

On the supposition that a natural secretion is the active agent Messrs. Warrick Brothers have made for me an extract of fresh lymph-glands warranted to contain, as far as possible, the vital qualities of the living organ. I have administered this to sundry cases with apparent benefit and never with any bad symptom. A gentleman seen in July, 1897, going down hill very fast with advanced cancer of the stomach, and very unlikely to survive beyond November or December, had his life prolonged until last April. I hope later to furnish further details. I have no facilities whatever for physiological research. The object of my letter is to appeal to some competent physiologist to take the matter up and to test it in the laboratory. He would require to ascertain whether a secretion of the gland, as I suppose, is the active agent; or whether, on the other hand, the destruction is effected by a phagocytic action of the lymph-cells. Medicine is learning more and more to seek its best weapons in the natural secretions of the body itself. The above principle tallies with the most recent lines of advance.

I am, Sirs, your obedient servant,

HERBERT SNOW.

Gloucester-place, Portman-square, W., Oct. 9th, 1898.

"SPHINCTER STRETCHING IN CONSTIPATION."

To the Editors of THE LANCET.

SIRS,—Mr. Sidney Vines's letter in THE LANCET of Oct. 8th brings into prominence the treatment of constipation by free sphincter stretching. It is a method well known but too little practised. If carried out in suitable cases it greatly assists and in many cases absolutely cures perplexing constipation. In my book on Diseases of the Rectum, sixth edition, I have devoted a chapter to Persistent Constipation considered from a Surgical Point of View. In a letter of this kind the subject is too lengthy to enter into fully.

In children constipation is often caused by a congenitally small but otherwise normal anus. Sometimes the child has only just missed an imperforated anus and in these cases there will be found a rigid narrow ring just inside the anus. In adults fissure is a common cause of constipation. It starts the trouble in this way. The fissure sets up a spasm with hypertrophy of the sphincter and the hypertrophy in time causes the sphincter to become indurated and so it loses its elasticity, which does not recover even if the fissure is healed by palliative methods. Treatment by free dilatation or division of the sphincter—which causes it to return to its normal condition—will often cure bad constipation arising or kept troublesome from the above causes.

I am, Sirs, your obedient servant,

HERBERT W. ALLINGHAM.

Grosvenor-street, W., Oct, 10th, 1898.

To the Editors of THE LANCET.

SIRS,—In answer to the inquiry of Mr. Sidney Vines in THE LANCET of Oct. 8th I beg to inform him that during my residence of two years in Los Angeles, California, I learnt that sphincter stretching in obstinate cases of constipation in adults was by no means an uncommon procedure. I myself have adopted this method in two cases with satisfactory results. I am, Sirs, yours faithfully,

Macclesfield, Oct. 12th, 1898. J. WESTMORLAND.

"VITALITY."

To the Editors of THE LANCET.

SIRS,—Dr. Harry Campbell has answered his own question, "Whence comes the augmentation in the sum of vitality?" by telling us "from the food and oxygen conveyed (to the organism) from without." I know nothing about "the sum of vitality" and cannot conceive how food and oxygen can give vitality or add to it. I do not know how to measure or weigh vitality, which I believe to be without weight and immeasurable. I have said nothing about the creation of force, but have endeavoured to show why vitality cannot be derived from non-living matter or from force.

Dr. Harry Campbell asks, "What becomes of the vitality of an organism after death *unless it be transmitted (transmuted?) into some chemical, physical, or kindred force?*" I do not know, but in the present state of knowledge must deny the possibility of any such transmutation. The instant Dr. Harry Campbell or anyone shows that any such transmutation does occur I shall, of course, give up the idea of vitality and very much besides of what I now believe to be true. I certainly hold that no living matter in nature possesses structure—not even that "destined to develop into a Newton or a Shakespeare."

"Structure" as referred to by me in various papers and books has been *seen* by myself and can be *seen* by all who can use the microscope. "Structureless" is that in which no structure can be discerned when examined in the same way by the same magnifying powers.

I think I have proved that all "structure" in living nature has been formed from *Structureless Living Matter* and that the arrangement, character, composition, and action of all structures, tissues, and organs of all organisms are determined by changes in the living matter caused by the *direct action* of vital power upon the matter. Tissue, structure, does not form or add to itself, but living matter may form it and many other things. Muscle, nerve, fibrous tissue, &c., were all once in the state of structureless living matter.

Lastly, I do believe that the "immaterial" does act, has acted, and will continue to act upon the "material" in every particle of matter that is alive, even though, as Dr. Harry Campbell assures your readers, by "many great thinkers" my "position" has "been regarded as untenable" and by himself as "wholly illogical."

I am, Sirs, yours faithfully,

Oct. 9th, 1898. LIONEL S. BEALE.

To the Editors of THE LANCET.

SIRS,—Having read Professor Virchow's Huxley Lecture and also Dr. Beale's recent papers on Vitality one wonders what the author of the latter will have to say on one of Dr. Virchow's particular propositions: "The cells of living organisms are composed of organic, chemical substances which are not themselves alive but the mechanical arrangement of which determines the direction and power of their activity." Dr. Beale in his papers would lead us to infer that with Paracelsus he believes each living unit has a

Digitized by Google

spiritus which, however, is not of the supernatural tinge of the Paracelsian world but is rather a form of energy alignable with physics and chemistry. Dr. Virchow scouts the idea. Who is right, the German or the Englishman?

I am, Sirs, yours faithfully,

JOSEPH H. ROWE, M.B. Aberd.

Cowling, Yorkshire, Oct. 11th, 1898.

THE PUBLIC APPLICATION AND USES OF BACTERIOLOGY.

To the Editors of THE LANCET.

SIRS,—In reading the interesting leading articles at pp. 882-84 of THE LANCET of Oct. 1st one cannot help feeling that their writer has, doubtless unwittingly, done much less than justice to the eminent bacteriologist who is admittedly the pioneer in this country of the practical application of bacteriology to purposes of local public health administration and commerce. I refer to Professor Delépine of Owens College, who, as long ago as 1891, assisted the Manchester Public Health Department with his special knowledge, and in 1892 suggested to Dr. Tatham an official arrangement for the bacterial examination of diphtherial products and the like. In the summer of 1893 Professor Delépine's aid was invoked in the investigation of certain choleraic cases in Manchester and in 1894 the borough of Stockport was materially assisted by his advice and skill in regard to its water-supply. During the following summer (1895) a definite arrangement was entered into between Professor Delépine and the corporation of the last-mentioned town for the systematic bacterial examination of doubtful diphtheria cases. A little later a similar arrangement was made by Manchester and more recently by most of the other large Lancashire towns, and at the present moment Professor Delépine is fully realising his cherished desire that his splendid laboratories at Owens College should exist, not merely for academic purposes, but for the very real benefit of suffering humanity in the district of which the college is the scientific centre. The work has been with Professor Delépine entirely a labour of love; he has ungrudgingly devoted time, money, and his great abilities to its development without one single farthing of personal remuneration. He has assisted many other towns (Liverpool, Edinburgh, Belfast, Aberdeen, &c.) by sending them all the information they required and a complete account of his procedure, and in many public health matters on which he is specially competent to advise he is the kind and ready "guide, philosopher, and friend" of every health officer who has occasion to consult him. Surely, then, it is hardly fair that in regard to the bacteriological public health service of the country his work should be placed in a second line, so to speak, with that of cities such as Liverpool, and commercial ventures such as the Clinical Research Association, which have merely followed the lead he has so ably and modestly given them. *Palmam qui meruit ferat.*

I am, Sirs, yours faithfully,

Health Office, Stockport, Oct. 9th, 1898. CHARLES PORTER.

WHAT IS "FIRST AID"?

To the Editors of THE LANCET.

SIRS,—To prevent the remedial assistance of "first aid" passing beyond its bounds and encroaching upon remedial treatment I have found it desirable as well as necessary to define what "first aid" really consists of. As this definition might be of use to many of your readers I herewith enclose the same. "'First aid' consists in the immediate relief of suffering and the temporary dressing of all injuries sufficient to enable the sufferer to proceed to where authoritative advice can be obtained from some qualified medical man or to remain on the spot when removal is unjustifiable until that advice can be obtained."

Under this comprehensive definition the arrest of hæmorrhage, the temporary application of splints to fractures, the first dressing of burns, and the application of antiseptic dressing to wounds would take first place. Immediate assistance would include the resuscitation of the apparently dead and the first succour requisite in cases of poisoning or fits. The immediate relief of suffering would include the giving of one dose of medicine for diarrhœa, colic, or other severe pain, as well as for shock, collapse, or temporary failure of the heart's action. No redressing of wounds or injuries nor operative interference of any kind is here included; in fact, the surgical aid is limited to what would be done by bearers at the front on a battlefield before the injured are sent to the base or station hospital for final redressing and surgically approved treatment.

I am, Sirs, yours faithfully,

Devonshire-street, W., Oct. 11th, 1898. SAMUEL OSBORN.

"GAS AND AIR."

To the Editors of THE LANCET.

SIRS,—I shall be very happy to show Dr. Flux my gas apparatus—now, alas, over twenty years old—by which he need not employ any napkin over the face or touch the patient's face with any of the apparatus. I have never suggested this very old method to my colleagues, much less the public, as I do not think the fees admit such a waste of gas. It reminds me of a letter I once received from the late Mr. Clover, who was taken in (by the recommendation of the committee of the British Medical Association) to use dichloride of ethidene, in which he related that a case had cost him 30*s.*, and that out of a two guinea fee. *Verb. sap.*

I am, Sirs, yours faithfully,

TOM BIRD,

Instructor in the Use of Anæsthetics to Guy's Hospital.

Brook-street, W., Oct. 11th, 1898.

THE ETHICS OF CLUB PRACTICE.

To the Editors of THE LANCET.

SIRS,—I should be glad to have an expression of your opinion on the following case.

I have been surgeon for over thirty years to a very large friendly society and my connexion with this society has always been most amicable till about twelve months ago. Then I was called in to see a member of the society suffering from quinsy. I saw him on the Monday morning and promised to call again on the Tuesday morning, but owing to stress of other work I was unable to get there and sent my assistant (M.R.C.S., L.R.C.P. Lond.) to see the man in the afternoon. (According to the patient's own statement the man was not seen for 26 hours.) On arrival at the house my assistant was told that the patient had called in another medical man who lived nearer. In the evening this medical man telephoned to me and I said I was quite willing he should take the case, and I remarked that to me it was a club case, but he must see he got his fees. I have since found that the throat trouble disappeared in a day or two and then brain symptoms set in—it was thought as a result of an accident received some months previously. The medical man in attendance wished for and obtained a consultation with a surgeon in the town with a view to trephining and the patient was removed to the infirmary for operation, where he fortunately recovered without operation in a few days. But I heard nothing more of the case from the time the second practitioner was called in till a few weeks later, when the patient wrote a letter to the secretary of the society in which he complained of neglect, and demanded from me payment of the second medical man's bill and the consultant's fee (amounting altogether to six guineas) and said he thought the way he was "treated was not fit for any human being" and he further complained of my sending my assistant. I refused to pay the bill and denied neglect. I consider I was under no contract to see the man at any given time, although I promised to call in the morning. It is impossible to work a practice on these lines and the medical man himself must, in my opinion, be the best judge as to the relative urgency of each particular case.

The second practitioner who was called in, in reply to a note from me, writes as follows: "In answer to your letter I may say that when called to see the man S—— I found him suffering from acute tonsillitis, and in following out my routine practice in such cases I put him on anti-rheumatic treatment with a gargle of guaiac., &c. If I remember correctly the quinsy had cleared up by the next evening; at no time was it a bad one nor did it tend to suppurate. I should say that it was a rheumatic throat pure

Digitized by Google

and simple. When I first saw S—— he was a bit excitable, but it was not until after the throat cleared up that I noticed symptoms of brain irritation. Thinking that an operation would relieve the symptoms I called in Mr. A—— (surgeon). We both were of the opinion that an injury S—— received by walking against a peg in the dark was the exciting cause of the irritation. He was removed to the infirmary with the view of being watched carefully for localising symptoms when trephining was to be done, but luckily the case cleared up without. The case in the first instance was perfectly simple and straightforward. The brain irritation coming on after the tonsillitis was a coincidence, as I should say it would have come on in any case. The throat probably had a turn for the better before I saw him; hence the rapidity with which it cleared up."

What I want to know is, can I be compelled to pay this account? I am, Sirs, yours faithfully,

Oct. 11th, 1898. BETA.

MAIDSTONE AFTER THE EPIDEMIC.

(FROM OUR SPECIAL COMMISSIONER.)

A YEAR has now elapsed since the great typhoid fever epidemic of Maidstone. It is time, therefore, to inquire what practical lessons have been learnt and applied as the result of this calamity. As a rule epidemics prove an efficient form of chastisement—they are sometimes a blessing in disguise. They awaken the local authorities to a proper sense of their duties, they make the population realise the need of good sanitation, and public improvements are then undertaken which formerly would not have received the sanction of the ratepayers. An epidemic often conveys the moral that good sanitation, though expensive, is, in the long run, the truest form of economy. How far has this been the case at Maidstone? Of course, much time has been spent in discussing the cause of the epidemic. This is well and needful in its way, but such theoretical discussions are often apt to be taken as an excuse for postponing the application of practical measures. In the present instance there has been a tendency to gravitate towards two opposite extremes. On the one side the water is considered not merely the principal but almost the only cause of the epidemic. Others, and especially the friends of the water company, are anxious to show that the epidemic might have been due entirely to the condition of the drains and that there is no positive evidence to prove that the water was specifically contaminated. The truth probably lies between these two extremes. The defective condition of the drains may have rendered the population susceptible to typhoid fever; and when the water was contaminated this receptivity was made manifest by the rapidity with which the disease spread. But there is evidence to show that the disease continued to spread when there is every reason to believe that the water was no longer contaminated. From the commencement of the epidemic at the end of August, 1897, up to Jan. 20th of this year, when the last case occurred, there were altogether 1908 cases of typhoid fever notified. Allowing for the period of incubation, the effect of cutting off the supply of water from the sources stated to have been contaminated should have made itself felt by Oct. 10th, and it was from Sept. 9th to Oct. 5th that the great majority of the cases occurred. The epidemic went from bad to worse up to Sept. 20th and the improvement, though slight at first, commenced before any alterations were made in the water-supply. After Oct. 10th, when the effect of cutting off the suspected water-supply should have been felt, there occurred 357 cases. Thus the number of cases decreased while the people were still drinking the bad water, and they continued after they had ceased drinking this water. Probably the water was the vehicle by which the epidemic was so widely and suddenly spread, but it was not the only cause. This, nevertheless, is quite sufficient to warrant a severer control being exercised over the water-supply.

The first good result of the epidemic is the determination of the town council to obtain powers for the compulsory purchase of the water companies' property and thus bring the supply under their own control. But it would be a fatal mistake to imagine that this is all that need be done. The borough surveyor has very wisely urged the necessity of a house-to-house inspection of the whole town, and by this he means that every domestic drain is to be submitted to the water test where possible and to the smoke or "stink test" where water cannot be utilised for the purpose. This, indeed, has been already done with regard to a third of the houses and is one of the most useful and practical measures which could be adopted. Unfortunately, and in spite of the terrible warning received, the landlords are still in many cases very recalcitrant. In 1892 the medical officer of health reported that two-thirds of the houses were not properly drained; and it may safely be said that at the time of the epidemic half the closets in the town had no water-supply. These closets were only flushed by hand—that is, when the inhabitants thought fit to empty a pail of water into the drains. It is obvious that notices should be served on the landlords of all these houses to compel them to apply to the closets a 2-gallon waste preventer flush tank receiving a constant supply of water. Efforts have been made in this direction, but they have not met with the success which might be expected after the terrible lesson received. Notices to provide water for the closets have been served by the sanitary inspectors, but they are carried out very slowly. On the other hand, the town council hesitates to prosecute. Nor do the population appreciate the laws enacted for their own protection. Thus, for instance, when the vendor of milk proved to be adulterated was acquitted because of some legal quibble the people in the court applauded. There is still much narrow-mindedness prevalent among the population. The interests of the till too often predominate, and the petty tradesman fails to see that it is his duty to submit to some inconvenience and control so that the interests of the community at large may be protected. The milkman may desire to adulterate his milk, but he may not be so anxious to eat tuberculous meat. Yet the previous year the town council failed in a prosecution in respect of an alleged sale of diseased meat. If the butcher could only be made to understand that he has to drink adulterated milk and the milkman that he has to eat tuberculous meat there might be less applause in the court on the acquittal of the tradesmen. But this view of the situation seems to be too broad and far-reaching to come within the narrow mental grasp of some of the inhabitants. The pity of it is that the magistrates show that they are inclined to let matters slide instead of being eager to apply the law on every possible occasion. The lukewarmness of the magistrates has to a great extent paralysed the local authority. This was the complaint made before the epidemic, but it was natural to expect that such a disaster would have brought about a great alteration and that the magistrates would now have readily convicted whenever there was any transgression of the sanitary laws. Such, however, is not the case and the town council still hesitates to prosecute. As a consequence the work of supplying water to the closets is only progressing slowly.

To exercise a better control over domestic drainage it is proposed to permanently increase the sanitary staff at Maidstone. All new drainage is submitted to the water test, which is applied by the sanitary authority before anyone is allowed to inhabit the newly built house. When the same has been done to all the old houses and a proper supply of water provided for flushing purposes a very great improvement will have been realised, but the magistrates must give more efficient help in the accomplishment of this work. There will then still remain the question of the public sewers. It is proposed to dig up all the old brick sewers which existed previously to the adoption, some twenty years ago, of the general drainage scheme and replace them by hardware pipe drains. Doubts, however, may well be entertained whether this is sufficient. The fact that a sewer is of comparative modern build does not prove that it is free from defects. There is reason, on the contrary, to believe that some of the sewers of the new drainage scheme were badly laid and constructed, and these as well as the older sewers require repairs, if not reconstruction. Then there is the question of the ventilation of the sewers. In dealing with the epidemic last year I pointed out that the districts affected with the fever corresponded, not merely with the distribution of the Farleigh water-supply, but also with the higher levels of the town. It then occurred to me to suggest that perhaps the sewer air had a tendency to travel upwards and that therefore the houses on the higher levels were more impregnated

Digitized by Google

with emanations from the sewers than those situate lower down; indeed, it was most remarkable that the low-lying districts were almost entirely exempt from the fever. The only answer made to this suggestion is that the direction of currents of air in sewers is frequently from the higher to the lower levels. It is difficult, however, to see what this most obvious remark has to do with the question. Surely no one would be so foolish as to urge that currents of air always went in the same direction; it would be as reasonable to state that the wind always blew from the same quarter. The point is whether, at the higher levels, there is a greater escape of sewer air in the houses and streets than in the lower districts and at what time of day does this escape take place. The downward current of air is likely to be most frequent when there is the greatest flow of sewage, for the air is attracted by the water current. As the current decreases in bulk and strength the air is more free to follow its natural bent and travel upwards. This is more likely to happen at night, just at the time when vitality is reduced by sleep and the inhabitants are more susceptible to any noxious influence. Then, again, it is when the sewers are empty or nearly empty that the sewer air is likely to be affected by the deposits on the sides or walls of the sewer. Thus the outward flow of air takes place at the worst moment and this it is which should be considered when comparing the high with the low levels. Therefore the question arises whether some measure should not be adopted so that the sewers in the higher levels of the town should not serve as ventilating shafts for the sewers in the lower levels. This is the more important as it is now proved that several hundred cases of typhoid fever were not due to water contamination, though the great majority of these cases did occur in the higher districts of the town. In the conclusions of the Local Government Board report on the epidemic it is stated that probably Oct. 10th is too early a date for the limit of the influence of the Farleigh water-supply; Oct. 18th is suggested instead, and even then there remain 280 cases due to causes other than the Farleigh water-supply. But if 280 cases occurred and were due to other causes after this supply was cut off, how many cases due to other causes occurred before the Farleigh water-supply was cut off? It is absurd to conclude that these other causes came into operation only after the water from Farleigh was cut off. The probabilities are that when this was done their force was in a great measure spent, just as the force of the contaminated water was to a large extent exhausted and this some time before the effects of its suppression could be felt. But with regard to these other causes, whether partially exhausted or otherwise, whether acting during the distribution of the Farleigh water or after the supply of that water had ceased, in both and all cases the victims were nearly all residents living on the higher levels. Now, the old brick sewers which it is proposed to replace by hardware pipes are nearly all on the low levels; therefore this measure, though good enough in itself, does not meet the case.

The policy of the town council is to obtain a loan in order to purchase the waterworks, to rebuild the old brick sewers, and to increase its sanitary staff. This is all very good so far as it goes, but, as just indicated, it does not deal with all the phases of the problem at issue. It is also unjust to seek to spread the repayment of the loan over a long period of years. The blunders, I might almost say the crimes, have been committed by the present generation and the penalty must be paid by them. The inhabitants of Maidstone have neglected their public duties, they have consequently brought upon themselves a public calamity, and they want to relegate to the next generation the care of paying at least a part of the cost. Even now they are not doing their duty in full. There is unjustifiable delay in providing flushing apparatus to household drains, and transgressors against the laws of health are not punished with quick and certain speed. There is no ground, therefore, for putting in a plea to be relieved from the burdens which are the natural consequence of past and even present neglect. The true position of affairs must be looked boldly in the face. In the long run this will be the cheapest as well as the best policy.

NEWPORT (MON.) WATERWORKS.—Up to the present the expenditure by the Newport Corporation on the Wentwood waterworks scheme has been £128,228. The works are reported to be progressing satisfactorily.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Medical Reform in India.—The Progress of the Plague.

THERE being absolute freedom of medical practice in India qualified men have to contend against an unlimited competition from quacks. As the public and the State to a certain extent call for some guarantee of education and knowledge the same feeling has arisen here as in England that irregular practice should be put a stop to. The same arguments apply in the one case as in the other. There is at present no registration but this might be provided for at the same time as the suppression of any further creation of quacks. In the city of Bombay there are about half a dozen civilian British practitioners, there are the officers of the Indian Medical Service holding civil appointments, who are allowed private practice, and there are about 80 native qualified practitioners. The quacks and unqualified men are numerous, but their exact number is difficult to estimate. It has been urged also, as so many native practitioners have been educated in England, several of them holding very high qualifications, that some of the teaching and hospital appointments should be thrown open to competition. At the present time these posts are held exclusively by officers of the Indian Medical Service.

The course of the third plague outbreak in Bombay has shown a sudden and unexpected improvement. While it has been gradually developing week by week until for the week ending Sept. 13th the number of deaths from plague was recorded at 175, the number for the past week has fallen to 126. The total general mortality (748) has fallen also, although it is still considerably above the average (523). There is no cholera, the cases of remittent fever recorded are much fewer, and there are fewer deaths from phthisis and diseases of the respiratory organs. The present death-rate is 45·37 per 1000. A steady development of the recrudescence was looked for and perhaps, after all, the diminution may be only temporary. It is argued that the machinery for registration is improved, that from the absence of compulsory segregation the people are less afraid of plague and its consequences, and that consequently there is less concealment of cases. Notwithstanding the withdrawal of all severe measures the plague authorities are active. No less than 6543 houses were inspected last week, 326 were disinfected and, most important of all, 50 were vacated. These measure have been going on steadily for some time and it i probable that the continued vacation of the worst houses is now showing good results. In the Dharwar and Belgaum districts the epidemic is raging with increased severity. In other parts of the Presidency it is better. A record of 3731 cases and 3134 deaths in one week shows, however, the extreme virulence of the disease. Of these numbers Belgaum contributed 745 cases and 557 deaths, and Dharwar 1642 cases and 1300 deaths.

A fresh example of the value of prophylactic inoculation is given by the action of the Southern Mahratta Spinning and Weaving Company with regard to their employés at Hubli. Out of 1173 persons on the muster roll 1040 were twice inoculated, and of this number 22 died from plague, giving a mortality of only 2·1 per cent.; of the 58 once inoculated 8 died, giving a mortality of 13·8 per cent.; and of the 75 who refused inoculation 20 died, giving a mortality of 26·6 per cent. At Dharwar inoculation is now proceeding actively.

Calcutta being almost free from plague the staff has been largely reduced. The general mortality keeps low. Madras has now been admittedly attacked, as what are termed indigenous cases have occurred in the Anantapur and Bellary districts. In Madras city itself the general death-rate is abnormally high, being 56·3 per 1000, against an average of 48·1. Out of the 490 deaths recorded for the past week 41 occurred from cholera. There were no recorded cases of plague. Endeavours are being strenuously made to introduce inoculation into the various divisions.

Sept. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mercer's Hospital, Dublin.

THE dispute between the board of governors of Mercer's Hospital and the Dublin Corporation has recently been revived. It will be remembered that the municipal authorities refused many months ago to continue their annual grant of £300 to that hospital unless three members of the corporation were elected as annual governors of the institution. The hospital authorities replied that the terms of their charter rendered it impossible for them to comply with the wishes of the corporation. The matter, as far as the public was informed, remained in that condition until, at a meeting of the board of governors of Mercer's Hospital, which was held on Oct. 4th, a notice of motion was handed in: "That the governors of Mercer's Hospital regret that the Dublin Municipal Council, by withdrawing from the hospital the usual grant out of the Corporate funds, have inflicted a serious injury upon the poor of this city, and they feel bound on behalf of the poor to appeal from the municipal council to the Local Government electors of the city of Dublin." This elicited a letter from the chairman of the Finance and Leases Committee of the corporation, which appeared in the morning papers of Oct. 7th, in which it is stated that—

> The vote in favour of Mercer's Hospital has never been withdrawn. It is obtainable at any time that the governors comply with the very reasonable request of the corporation that three members of the corporation, nominated by the municipal council, should be elected to seats on the board. This the governors so far have declined to do. The position therefore is that sooner than elect as vacancies occur three governors from the members of the municipal council the board of Mercer's Hospital will deprive that institution of the sum of £300 per annum. The names of the members of the corporation nominated have been supplied to them long since. In exchange for a notification of compliance with this very reasonable condition the Finance and Leases Committee will issue a cheque for £300.

One of the governors of the hospital, Mr. Theodore Ryland, replied at once that they,

> The governors, were willing to comply with the request of the Municipal Council and were ready to elect the three members chosen by the Council, and so stated in a letter dated Oct. 25th, 1897, addressed by the Registrar to the Town Clerk. In order to carry out their intention in the proper way the governors took the opinion of eminent counsel as to the manner in which the three representative governors should be elected and were advised by him that they were bound by their charter and have not power to comply with the wish of the Municipal Council, however anxious they might be to do so.

Other letters and even leading articles have appeared in the public journals, but the difficulty seems as far from satisfactory solution as ever. The charter of the hospital will only permit the election of governors for life, while the expedient of electing for life with an understanding that the governors would retire after one year has been declared by eminent counsel to be illegal. No one seems to have suggested that the charter of the hospital might be altered in order to legalise the election of annual governors. If the board of Mercer's Hospital proposed to take the necessary steps the grant from the corporation would doubtless be paid at once.

St. Vincent's Hospital, Dublin.

The annual dinner of the medical staff and past students of St. Vincent's Hospital took place on Oct. 10th, when the proceedings were enlivened by a rather novel speech from Mr. M'Ardle. Referring to the question of what fee should be charged to a man who, though not a pauper, could not afford a guinea, Mr. M'Ardle is reported to have said:—

> There was a notion abroad that unless a man stuck up for a guinea fee his status was lowered. He (Mr. M'Ardle) would wish it to go forth from that meeting—if they all agreed to it—that there was no indignity in accepting such a fee as your *clientèle* could afford, and there were no by-laws of any club or association of their profession that limited in any way the fee for a medical practitioner. The rules and regulations of professional dignity in regard to fees were made for the purpose of circling around the higher members of the profession and keeping a barrier between them and their younger brethren. The sooner that that barrier was broken down the better it would be not alone for the profession themselves but also for the public.

There are many members of the medical profession here who do not share in the views of Mr. M'Ardle, but to whom it seems improper and unfair to his less fortunate brethren that a hospital visiting physician or surgeon of position should give advice for a lower fee than £1 or for practically anything that he can get.

The Meath Hospital and County Dublin Infirmary.

The inaugural address for the session was delivered at the Meath Hospital by Dr. Ormsby, one of the surgeons to the hospital, on the afternoon of Oct. 10th. The Lord Mayor occupied the chair, and a large audience, which included the President of the Royal College of Physicians and the President of the Royal College of Surgeons, was present. Dr. Ormsby's lecture, which dealt with the changes which had taken place in medicine during the last 100 years of progress, contained amongst many other instances an allusion to the system of bleeding for almost every ailment which prevailed a century ago. Lord Powerscourt, who was present, remarked that he remembered as a child "his father, who was ill of consumption, being bled constantly."

Pauper Nursing in Workhouses.

At a special meeting of the Armagh Guardians, held on Oct. 4th, to consider a letter from the Local Government Board in which they stated that they could not permit the continuance of an arrangement under which paupers with illegitimate children are employed in immediate attendance on sick persons of good character, and asking the guardians to reconsider their decision on the matter, failing which they would have no option but to call upon the medical officer to exercise the power vested in him by the rules and to see that the Board's regulations are carried out, an interesting discussion followed. The guardians decided to direct the master of the workhouse to remove all healthy paupers who have illegitimate children from the sick wards and to locate them in the department of the house to which they belong, and where such inmates are required to discharge menial duties in the infirmary, that they are to do so under the personal supervision of the nurses or paid attendants and to return to their department in the main building when no longer required in the sick wards. They further decided to write to the Local Government Board that they are of opinion that the nurses and attendants already appointed are quite sufficient for the duties which have to be discharged. Accordingly they emphatically decline to appoint any more until a trial is given to their suggestions. The whole question resolves itself into one of whether or not there shall be pauper attendance or nursing, and it is certain that the Local Government Board will insist that the pauper attendance must cease.

Clonavaddy Dispensary.

Mr. Gill, L.R.C.P. & S. Edin., has been appointed medical officer of Clonavaddy District of the Dungannon Poor-law Union, in the place of Mr. Thomas M. Jamieson, L.R.C.S. Irel., who lately retired after forty years' service

Resignation of Dr. Croker.

One of the oldest medical practitioners in Belfast, Dr. Croker, has owing to failing health been obliged to resign his appointment as medical officer of the Castlereagh Dispensary, a post he has held for thirty one years.

The Monaghan Water Scheme.

The Toghan scheme for supplying Monaghan with water has been adopted. By this plan a reservoir could be made by excavating about 10 acres and there would be an altitude of 220 feet. The site would be 3¼ miles distant from Monaghan and the pipes could be laid principally along the road, and the estimated cost would be about £7075. The Local Government Board have still to sanction the scheme.

The Notification of Infectious Diseases

One of the Belfast morning newspapers, in giving a report of a meeting of the City Health Committee, which, they add, they learned unofficially, states that the question of the notification of the infectious diseases again formed the subject of discussion, and the action of certain medical practitioners who, it was alleged, had reported cases as typhoid fever which were probably "bogus" was criticised. It was suggested that these medical men should be prosecuted for obtaining money under false pretences, and some remarkably strong language was used concerning them by members of the committee. The chairman declared that there were undeniably some black sheep in the medical flock of Belfast, adding that the sooner they were pitched out the better. It was ultimately decided that a caution as to future conduct would suffice for the present. On public as well as professional grounds the action which certain members of the Public Health Committee are taking in reference to the

Digitized by Google

charges they are making against medical men is to be regretted, and instead of wasting their time in such a way they would be much wiser in trying to undo the terrible mistakes of the past. When the press, lay and medical, pointed out the insanitary condition of Belfast and when the outbreak of typhoid fever reached an alarming extent the Public Health Committee made their first charge against the profession. They said the medical men were duplicating the cases, forgetting altogether that in February, 1897, the medical officer of health at their request sent a circular to every medical man in Belfast calling attention to clauses in the Act which says that "every medical practitioner attending on or called in to visit the patient shall forthwith ..... send to the medical officer of health ..... a certificate ..... or shall be liable ..... to a fine not exceeding forty shillings." Further, the medical officer of health in this circular added: "As the benefits accruing from this Act will largely depend on the action of the members of the medical profession he would earnestly request their coöperation in the working thereof." The medical men had no other course, no matter how many saw a case, but to report it; if the Public Health Committee had a competent clerical staff any duplication of returns would have been corrected. The next charge against medical men is much more serious: it is that of reporting "cases as typhoid which were palpably 'bogus.'" This is a very strong charge to make and the Public Health Committee should give the names of the medical men whom they incriminate in order that they might have the right of making a defence. The truth is that the Public Health Committee, by making these aggravating insinuations, as well as by their apparent incapacity to deal with the very grave insanitary condition of Belfast, are losing completely the confidence of the public as well as of the medical profession, who could afford them so much help in dealing with a confessedly difficult problem. The sad part of the matter is, that typhoid fever is not being stamped out; on the contrary, it still is very prevalent in the city. The Public Health Committee should coöperate with the medical profession and should show their gratitude to the press and to medical journals like THE LANCET, which has taken such pains to point out the insanitary condition of Belfast and their duty regarding it.

The Belfast Asylum.

At a meeting of the Belfast Asylum Governors, held on Oct. 10th, a report of the Visiting Committee was submitted in which they reported with pleasure the marked improvements they had observed since their last visit eighteen months previously. The present medical superintendent, at comparatively small cost, has made wonderful changes in the Purdysburn Asylum. Further, they said they could not speak too highly of the improvements in the old building at Belfast, notably the new baths and the arrangements for carrying out the bathing. The committee say they confess they did not think it possible to effect such a transformation in the old building and they congratulate the medical superintendent on the energy, skill, and good judgment he has displayed in generally affecting such reform.

Oct. 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Congress of Gynæcology, Obstetrics, and Pædiatrics at Marseilles.

ON Oct. 8th the opening sitting of the Congress of Gynæcology took place in the large theatre of the School of Medicine. Dr. Pinard, of the Faculty of Paris, presided, and was assisted by Dr. Pozzi and M. Broca of the University of Paris. The opening address was given by the Mayor of Marseilles as a welcome to the members of the Congress. Dr. Pinard, who followed, described the objects of the Congress, one of which was to further the protection of women and children. He expressed the opinion that every large town should have an asylum for pregnant women and special provision for children of tender years. After him Dr. Pozzi, a member of the Senate, spoke on the subject of Gynæcology and laid down as an axiom that this branch of medicine was of special value in preserving the life of woman without neglecting the preservation of her creative faculty. M. Hoffa of Würzburg read a paper upon Orthopædics and drew special attention to the perfection at which this science has arrived in France. Professor Solovieff of Moscow said a few words of thanks to the Congress and Professor Jonnesco of Bucharest, the official delegate of the Roumanian Government, spoke very happily as to the reciprocity in thought and feeling which existed between the two countries. Lastly, Dr. Livon, the director of the School of Medicine of Marseilles, thanked all the members of the Congress for having attended in such numbers. The Congress is to last throughout the week. It is divided into three sections to deal with the following subjects:—Section 1: Gynæcology; President, Dr. Pozzi. Diagnosis and Treatment of Extra-uterine Pregnancy. Section 2: Obstetrics; President, Dr. Pinard. Auto-intoxication of Pregnancy. Section 3: Pædiatrics; President, M. Broca.

The Pasteur Institute.

On the third anniversary of the death of Pasteur, Professor Metchnikoff, the acting director of the Institute in the rue Dutot, owing to the absence of M. Duclaux and Dr. Roux, called together the professors, the medical men, the laboratory assistants, the administrative staff, and the servants of the Institute. With Professor Metchnikoff at their head they all descended into the crypt where rest the remains of the master and walked in solemn silence round his tomb. Opposite the Institute in the rue Dutot the administrative council is constructing a building upon a plot of land given by an anonymous benefactor, the expenses of which are defrayed by the gift of 2,000,000 francs (£80,000) made two years ago by the Baroness Hirsch. The material is red brick and the buildings are almost exactly like the Pasteur Institute except that they are one storey higher. They contain theatres and laboratories. For patients affected with diseases which have been specially investigated by Dr. Roux a hospital is being built at the end of the rue Vaugirard, and the director of it will be M. Martin, the brother of the architect in charge of the works. The opening, however, cannot take place before the end of 1899, and as a matter of fact there are only 20 workmen employed on the building at present. The foundations are nearly completed and but for the stoppage of work due to the strike it was hoped that the masonry work would have been finished before the beginning of the winter, so that once the roof was on work could have been continued during the winter, however cold it might be.

The Oil Motor Tricycle for Medical Men.

A question much debated among medical men at present is how far a carriage and horses may be replaced by the oil motor tricycle. In the review of the French Touring Club, Dr. Leon Petit said a greal deal about the evils of the tricycle at present in fashion. On the other hand, Dr. Boulle of Buis has written an answer full of figures showing considerable advantages in the tricycle. According to him a tricycle of 1½ horse power is far superior to a carriage. He balances his statement as follows: purchase price of 2 horses, 2 carriages, and harness, 3300 francs (£132); various annual expenses, 2400 francs (£96); primary expense of a tricycle, 1250 francs (£50). This would be second-hand, it is true, but it is quite possible to get a new one of the very first rank for 1500 or 1700 francs; upkeep, 730 francs (£29); to which must be added 150 francs (£6) for twenty days in the year when, on account of bad weather, Dr. Boulle has been compelled to pay his visits by means of a hired horse and carriage. The total expense of upkeep, therefore, amounts to 880 francs (£35). Dr. Boulle ran 20,000 kilometres (12,500 miles) over abominable roads without any serious wear and tear. The whole subject is of interest as clearing up in some measure a question of great importance to country practitioners.

The Increase in the Number of French Specialists.

At the congress recently held at Nantes Dr. Polo remarked upon the manner in which specialist practitioners have increased in France to a far greater degree than general practitioners. In Paris in 1892 there were 2125 medical men, of whom 234 were specialists. At Nantes at the same time there were 100 medical men and 7 specialists. At the present time the number of specialists is doubled in both those towns, although the number of general practitioners has increased in a very much smaller proportion.

The Training of the Corps de Santé.

The three days' training of the Corps de Santé took place on the plain of Avaron on Oct. 6th, 7th, and 8th, and the

Digitized by Google

members of the medical reserve, including the civil medical practitioners of Paris, took part in it. Everything had been admirably organised beforehand. The opposing forces were divided into two, one to attack the position on the plain of Avaron and the other to defend it. After the battle the Corps de Santé proceeded to pick up the wounded on the field, and to make the task of the bearers easier every wounded man was duly labelled with a ticket showing the nature of his injury, as, for instance, "fracture of the skull," "punctured wound of the thorax." The wounded men were told off to go to that ambulance which was specially appropriated to the gravity of their case and the urgency of their symptoms. Some were treated on the field itself, others were carried on stretchers to the ambulance of their own division, and others were sent to the temporary hospital—that is to say, the field hospital. On the day following various experiments were made in the transport of the wounded by means of ordinary country waggons transformed into temporary ambulances by means of special appliances, while other wounded were carried in the coal barges on the canal. A large crowd "assisted" at the manœuvres, which were very successful.

The Admission of Well-to-do Patients to Hospitals.

The action of Dr. Variot, as reported in my letter of last week, continues to occupy public attention, and the political press in general blames his conduct. They argue on the one hand that it is not possible for the medical man to decide merely by the dress whether the patient is indigent or not—which is a perfectly reasonable opinion, but it only proves that some steps ought to be taken by the administration of the hospital before the patients are admitted to get some proof of their poverty from would-be patients. But at the same time these papers uphold the dangerous theory that the medical officer of the hospital has no right to refuse gratuitous attention to anybody who comes, and some of them argue that the hospital ought to be perfectly open and free to everybody, whether poor or not. This extraordinary pretension would result in the State-supported hospitals coming into bitter conflict with the ordinary medical men in the town, who are already not so very well off, and for those medical men practising in working-class quarters, who already have to content themselves with very small fees, the result would mean ruin. To those practitioners who work among the higher class the loss would be very considerable if everybody had a right to gratuitous advice, for many of their patients would then come to see them at the hospital instead of consulting them at their own homes. The Director of the Assistance Publique, to whom complaint was made by the would-be patient of Dr. Variot, has referred the case to the governing body of the Assistance Publique, who will decide on the matter. Meantime the daily papers credit the Director with a policy which is certainly disquieting to medical men—namely, that it is intended to hang up in the consulting-rooms a box in which well-to-do patients may place a sum proportionate to their means and satisfactory to their consciences. The only result of this will be that non-indigent persons will be able to exploit the medical men in perfect security.

Oct. 10th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Egyptian Army Medical Staff.

THE medical arrangements of the late campaign were well organised and excellently carried out and reflect the greatest credit on Colonel Gallwey, C.B., who is now the fifth medical officer on the seniority list of the Egyptian army. The whole of the *personnel* were concentrated at the Atbara on August 20th ready for the forward movement. Captain Penton was made senior medical officer of the infantry division, and Captain Whiston, Captain Spong, Captain Jennings, and Captain Dunn were each placed in medical charge of a brigade. Each had under his orders 16 non-commissoned officers and men, a section of field hospital, all extra dressings, stretchers, cacolets, medical comforts, and a Congo chest. Every regiment carried with it a native medical man with his pocket case and morphia syringe, first field dressings, field panniers, medical comforts, and two stretchers per company with drilled bearers. Captain Hill Smith was made responsible for the mounted troops, which carried with them cavalry haversacks of surgical instruments, extra field dressings, and a mounted orderly with his belt full of drugs for emergencies. Captain Bray and two British non-commissioned officers were in charge of two hospital boats, carrying extra hospital equipment, tents, filters, and cooking and invalid necessaries. On the eventful fighting day, Sept. 2nd, the sections of field hospitals were not in action but were in their proper place with the main baggage camels. All the medical staff was ordered after the battle to concentrate at one spot with their wounded and the two hospital boats. This spot was fixed next morning at a place about four miles north of Omdurman and a hospital was then formed to accommodate 600. As a matter of fact the total number of sick and wounded during the first week after the battle was 584. All the day of the fight the wounded came dropping in and were attended to at the original zareba, the Nile bank, and on the barges. The total number of wounded was 286, half being blacks and the other half Egyptians. The whole number of killed and of those who were so dangerously wounded that they died within a week after the battle was only 49. Only 50 of the Egyptian army were wounded in the zareba and 6 were killed; the remainder of the wounded were injured at the time when the Dervishes tried to rush Colonel Macdonald's brigade. It is an old story now how well he and his Soudanese behaved at that time, but honour must also be given to Colonel Pink's battalion of Egyptians who formed part of that brigade. There were only 8 British medical officers at the battle, with 18 native medical men and apothecaries and 150 non-commissioned officers and men. Captain Spong and Captain Hill Smith have now been in all the engagements since Dongola and are already entitled to 6 clasps, being among the 13 officers who will receive the maximum number of clasps. Among other work done by the Egyptian army 8 gunboats were equipped with medical and surgical necessaries, though the English army had to supply the medical officers. 2 communication hospitals were established at Nasri Island and Gebel Ryan for the reception of the sick during the advance. When the British troops had left Omdurman 150 Egyptian sick were at once sent to Cairo, and now 100 slightly wounded Egyptians have been removed to Cairo, whence they will be sent to their village homes to convalesce. The black sick and wounded have all been left at Omdurman, because they are quite at home in that climate and because the whole of the medical staff is still concentrated there. The wounded are in tents on clean desert ground and the sick are in houses supplemented by shaded huts of straw and wood built by the Soudanese.

Present Medical Arrangements.

Captain Penton remains as the senior medical officer at Omdurman with Captain Jennings, Captain Spong, and Captain Dunn. Captain Whiston is with the mounted troops at Wad Hamad, Captain Hill Smith is marking time at Fashoda, Captain Bray at the Atbara, and Captain Wanhill at Wady Halfa. While all this has been going on Captain Fleming has been at Kassala, and now he telegraphs that all his 50 wounded are doing well. At the recent battle of Gedarif the Kassala garrison had 40 killed by the Dervishes, but no British officer was hurt. Now General Hunter has gone up the Blue Nile to join hands with Kassala and the railway between Atbara and Khartoum is being surveyed on the east bank of the Nile. These 200 miles will be in working order in about a year's time and where the Atbara is low a bridge will be built. As an instance of how rapidly events follow just now in the Soudan it may be pointed out that 800 blacks who fought with the Dervishes against us less than a year ago at the Atbara formed part of the Egyptian army which smashed the Khalifa last month. Of these 800 only 13 tried to desert; they were shot.

Port Said Hospitals.

The Egyptian Government hospital with its 100 beds is now under the care of Mr. W. B. Orme, Mr. F. R. Milton having been promoted to the post of junior surgeon at Kasr el Aini Hospital, Cairo. The hospital does very good work and natives come from great distances to get surgical aid. Dr. E. Cuffey, at present a naval surgeon at Crete, has been elected to the post of resident officer at the British Hospital, to succeed Mr. Foster-Foster, who died recently. This hospital is a wooden building of about 30 beds which has almost served its term of years. It is unbearably hot in the

Digitized by Google

summer, but there do not seem to be any funds forthcoming to provide a permanent structure.

Cairo, Oct. 3rd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Infectious Diseases in New South Wales.

MEASLES, scarlet fever, and influenza are exceptionally prevalent in New South Wales. Scarlet fever alone is notifiable and the number of cases reported for the fortnight ending August 12th was 230, and the same number was reported for the preceding fortnight. Measles seem to be almost pandemic. The disease is raging in all the Australian colonies and has broken out in Fiji, where it is exceedingly fatal to the native population. In New South Wales, as in Victoria, a large proportion of adults have been attacked (about 1 adult to 9 children has been estimated as the probable proportion). Influenza has also been again very prevalent in New South Wales, chiefly in its catarrhal form, while pneumonia as a sequel of all three forms of epidemic disease has been a prominent factor in the mortality bills. It need hardly be said that the general medical practitioner has been kept very busy in the chief centres of population in New South Wales during the last month or two.

Metaphysical Healing and its Results.

Some time ago a so-called "Professor" Mills and his wife arrived in the Australian colonies from America as apostles of "Metaphysical Healing." They had a moderate amount of success in Melbourne, but in Adelaide the movement "caught on" in a remarkable manner. A "Metaphysical Society" was founded and a sort of hospital, known as the "Home of Truth," was established, where patients willing to submit to the new treatment were received. Everything went on satisfactorily until the beginning of August when a somewhat sensational case occurred. A girl who had undergone several operations for hydatids and had made arrangements for another operation by Dr. Poulton was induced to go into the "Home of Truth" without her mother's knowledge. When the mother discovered her and brought her home she was insane and had to be sent to the Parkside Asylum. Needless to say the hydatid was not cured. Her brother on meeting one of the founders of the "Home of Truth" gave him a sound thrashing, to which no resistance was offered.

Presidential Address.

In his address to the South Australian branch of the British Medical Association the retiring President, Dr. Anstey Giles, dealt at some length with the difficulties at the Adelaide Hospital, giving a *résumé* of the main facts of the squabble up to date and from the point of view of the old honorary staff. He denied emphatically that the action of the late staff was influenced by political considerations and he also denied that by the action of the staff on resigning the hospital patients were left without medical aid, as the staff expressly notified their willingness to attend until suitable arrangements were made for carrying on the work. Reference was then made to existing difficulties among members of the branch arising out of the hospital dispute. Some of the members of the branch had accepted positions on the honorary staff of the hospital and certain other members had requested the council to call a special meeting for the purpose of expelling the members who were on the staff. The meeting was held and decided not to adopt any extreme measures and in consequence seven of the most active members of the branch resigned. Dr. Giles regretted very much that these members should have been compelled by a stern sense of duty to such a course, but admitted that they had acted with the very highest motives and at great self-sacrifice in the interests of the profession.

Eye Specialists to Lodges.

The Council of the New South Wales branch of the British Medical Association having had its attention directed to an advertisement calling for applications from eye specialists to attend the members of a friendly society asked the opinion of the ophthalmic surgeons practising in Sydney on the subject. The following reply was received and approved by the Council: "At a meeting of medical men practising as specialists in the diseases of the eye it was unanimously resolved, 'That the Council of the B.M.A. should condemn the appointment of eye specialists by lodges and that the Council be requested to discountenance the introduction of the principle of club practice in connexion with special work.'"

Pulmonary Hydatids.

At the last meeting of the Medical Society of Victoria Dr. A. J. Wood read notes of three interesting cases of hydatid of the lung in children. In the first case the Russell-Bond method of treatment was adopted, the wound in the parietes being closed after removal of the endocyst; in the second case the wound was only partially closed but not drained; in the third case the wound was drained. All did well, but in the first case the recovery was most rapid, and Dr. Wood was of opinion that the other two cases might have been more satisfactorily treated by the Russell-Bond method. In the discussion which followed Mr. Russell objected to treating pulmonary hydatids by his method owing to the danger of producing general emphysema. Dr. Wood pointed out the danger of exploring pulmonary hydatids with a needle. Bronchial tubes open on the adventitious capsule and when the intracystic pressure is lowered the cyst is apt to rupture and the fluid contents escape inside the adventitia and then into the bronchi and so asphyxiate the patient. The risk of operating on pulmonary hydatids is also well exemplified in a case recorded by Dr. H. C. Hinder in the *Australasian Medical Gazette* for August. The patient was a girl, aged eight years. When a knife was passed into the cyst over the dulled area the opening was stopped with the finger and the fluid allowed to escape slowly. When about 1½ oz. had escaped she coughed and blood escaped from the mouth and from the cyst in large quantity and she died almost immediately. Post mortem it was found that the adventitia communicated directly with the left bronchus and pulmonary artery, each communication admitting a No. 12 catheter. During life the tense endocyst completely blocked the opening, but of course the moment the tension was relieved the artery was opened.

Inguinal Hernia in Childhood.

In a very able and thoughtful paper read before the August meeting of the Medical Society of Victoria Mr. Hamilton Russell strongly advocated the necessity of radical operation in every case of inguinal hernia in childhood. He maintained that in the normal and properly developed canal of a child where the funicular process is obliterated a hernial protrusion is impossible owing to the sphincteric action of the muscular fibres of the internal oblique. The main factor in the occurrence of inguinal hernia in childhood is a patent funicular process. Truss treatment fails to cause obliteration of this process and a patient so treated is always liable to the sudden descent of the hernia and especially to acute strangulation. The only satisfactory method of treatment and all that is required is to remove the congenital sac by operation.

Removal of Scapula.

The new operating theatre at the Melbourne Hospital was crowded to excess on August 25th, when Sir T. N. Fitz-Gerald removed the arm, scapula, and clavicle (by Berger's operation) for an enormous sarcoma of the upper end of the humerus which had followed an injury received three years previously. The interest in the case was the immense size of the growth, the anatomical relationship of the parts being greatly disturbed by its invasion of the axilla and root of the neck. The patient is doing well. In the *Inter-colonial Medical Journal* for August Dr. R. H. Marten records a case in which in April, 1896, he amputated at the shoulder joint the left arm of a woman, aged twenty-six years, for a spindle-celled sarcoma of the upper end of the humerus. In August, 1897, the growth recurred on the scapula, and on August 23rd he removed the scapula by a modification of Berger's method, the subclavian artery being tied at the end instead of the beginning of the operation. Recurrence took place in the lungs a year after the second operation and proved fatal. The original onset and each recurrence was coincident with pregnancy and her eldest child had sarcoma of the eyeball.

Digitized by Google

Dr. Marten believes the pregnancy influenced the growth and when the patient became pregnant after the second operation felt justified in inducing abortion.

August 28th.

Obituary.

MAURICE DAVIS, M.D. ST. AND., M.R.C.S. ENG., L.S.A., J.P.

ON Sept. 29th, at his residence, 11, Brunswick-square, Bloomsbury, in the seventy-seventh year of his age, Dr. Maurice Davis peacefully passed away. Born in Oxfordshire in 1821, he entered King's College, London, as a matriculated student in 1849 and received the diploma of Associate of the College in 1852. In the same year he received all his medical qualifications — M.R.C.S. Eng., L.S.A. Lond., M.D. St. And. On the completion of his curriculum he betook himself directly to the practice of medicine and threw all his energies into the building up of a splendid practice instead of seeking appointments at at his hospital and medical school. Had he sought such appointments he would doubtless have been as successful a teacher as he was a practitioner. In October, 1887, he was placed on the Commission of the Peace for the County of Middlesex and Liberty of Westminster and became by statute a justice of the peace also for the new County of London. By this appointment he became an *ex-officio* member of the board of guardians of the parish of St. Pancras. He served for a time on the committee of the infirmary at Highgate. He was a member of the council of the Metropolitan Branch of the British Medical Association and also of the board of directors of the Society for the Relief of Widows and Orphans of Medical Men. He occupied for some years a seat at the Jewish Board of Guardians until obliged to resign by stress of work, retaining, however, his connexion with the board through the sanitary and industrial committees as its medical adviser. For a considerable period he served as a member of the council of the Anglo-Jewish Association and of the medical staff of the Jewish Convalescent Home. Dr. Davis possessed literary gifts of a high order. He contributed to the *Sanitary Record* and a series of valuable communications on "Sanitary Defects in Houses" from his pen appeared in that paper from 1884 to 1890. In 1875 an interesting essay appeared in the *Jewish Chronicle* entitled "The Cosmopolitanism and Longevity of the Jewish Race." In some addresses for dramatic performances and extravaganzas he was happy in subjects and methods of treatment. These were written for the benefit of King's College Hospital and the Great Northern Central Hospital, of which latter he was a life governor. He possessed a technical and wide knowledge of architecture, and perhaps there is not a cathedral in Europe worth seeing which he has not visited. One of the truest of friends, ever ready to help in any difficulty, he was a staunch supporter of the honourable traditions of the medical profession and on every occasion displayed a whole-hearted loyalty towards his medical brethren.

He married in 1854 Esther, daughter of James Graham Lewis, founder of the firm of Lewis and Lewis, solicitors, Ely-place. On the death of his wife in 1891 he retired from the active duties of medicine, but not into idleness. He devoted much time to judicial work and especially (in his magisterial capacity) to the examination of lunatics. The number of cases examined in his district, together with those arising out of his duties as one of the committee of visiting justices at Holloway Prison, amounted to from 300 to 400 every year.

WILLIAM RUTHERFORD ANCRUM, F.R.C.S. ENG.

IT is with regret that we announce the death of Mr. William Rutherford Ancrum, which took place at his residence, St. Leonards Court, Gloucester, on Oct. 9th. For a very long period the name of Mr. Ancrum was closely associated with some of the most important matters of administration in the county of Gloucester, and it would be well nigh impossible to overrate the value of the public work which he accomplished. It is just three years ago since the state of Mr. Ancrum's health compelled his retirement, and deprived the county of his eminent services. He was taken ill at a meeting of the county council in October, 1895, and since then his health had been gradually getting worse.

The late Mr. Ancrum had attained the advanced age of eighty-two years, he having been born at the Manor House, in the village of Weston, near Bath, on Feb. 5th, 1816. He was educated at private schools and he entered University College Hospital, London, in 1834. In 1839 he took the M.R.C.S. Eng. diploma, and became house surgeon at the hospital. Three years later he went to Mexico, and was in practice in the city of Mexico and surrounding district for five years. In 1848 he was appointed surgeon to the Naval Hospital in Valparaiso, where he also had a large and lucrative private practice. He held that appointment for eleven years, coming home on one occasion to pass the examination for the Fellowship of the Royal College of Surgeons of England. On his return to England Mr. Ancrum spent three years in London. Early in 1863, having retired from practice, he purchased St. Leonard's Court, where he resided until his death. Two years after he had taken up his residence in the county he was placed on the Commission of the Peace for Gloucestershire and for thirty years he took an active interest in his magisterial duties, both as regarded the police-court and the quarter sessions, and on the death of Sir William Guise he became chairman of the Gloucester County Bench. Mr. Ancrum took a very great interest in the Gloucester Infirmary, of the governing body of which he was chairman for twenty-seven years, and on his retirement a special resolution was passed recording the invaluable services which he had rendered and the great practical good which had resulted from his wise administration during that extended period. Subsequently a ward in the infirmary was designated the "Ancrum Ward" in recognition of his distinguished services to the institution.

On the death of Mr. S. S. Dickinson in 1878, Mr. Ancrum was appointed chairman of the committee of Wotton County Asylum, and it was through his influence and direction that the Second County Asylum was built and successfully financed in 1882. He was elected chairman of the Barnwood House Private Asylum also in 1878, and under his guidance the institution was considerably enlarged and several important additions were made to the buildings. He was a member of several committees of the old court of quarter sessions and then of the county council, of which he was an alderman, and he succeeded Mr. Brooke Hunt as chairman of the prison committee of visitors. In 1852 he married the youngest daughter of Mr. Arthur Lewis, of Brighton, who survives him, and he leaves a family of three sons and two daughters. The funeral took place on Thursday, Oct. 13th, at Upton St. Leonards.

DR. JEAN CROCQ.

THE death of Dr. Jean Crocq occurred very suddenly in Brussels on Sept. 18th. The Brussels University loses in him one of its oldest and most eminent professors, and he was without doubt one of those who have contributed most fully to spread the fame of that University throughout not only his own country but also foreign lands. Dr. Jean Crocq was born at Brussels on Jan. 23rd, 1824, and studied at the Universities of Ghent and Brussels, obtaining the degree of Doctor of Medicine, Surgery, and Midwifery in May, 1848, and *docteur agrégé* in October, 1848. In 1849 he became prosector in the anatomical department and he published his great work on "White Swellings of the Articulations" in 1853. Of all his work this is without doubt the most important and that which placed him obviously on a par with his most illustrious colleagues De Roubaix and Thiry. In 1855 he was nominated extraordinary professor and in 1856 surgeon to the Grand Hospice, where he had charge of the wards for the aged until 1860, in which year he was made professor and visiting physician to the Hospital of St. Pierre. For twenty-five years he gathered around him a host of pupils attracted by his lectures and, dowered as he was with perfect scientific knowledge, with a prodigious memory, wonderful power of observation, and above all with a fluency of language, he was enabled to communicate to his pupils some portion of his own enthusiasm and to produce a profound impression by his

Digitized by Google

lectures which inspired his youthful hearers with admiration and warm affection for their master.

In his capacity of professor he occupied successively the chair of mineralogy and geology in 1861 and in 1866 that of general anatomy, and towards the end of 1868 he succeeded M. Le Beau in the department of pathology and therapeutics—a post he held for thirty years, to the end of his life, and in the carrying out of the duties of which he displayed an assiduity and earnestness which were universally recognised.

Having been elected a member of the Belgian Academy of Medicine in 1862 he took part in all the important discussions, notably that upon the case of Louise Lateau,[1] and those on the organisation and re-creation of faculties of medicine and the bringing about of a Central Institute for advanced studies. He was an indefatigable worker and almost to the last day of his life he devoted himself to the duties which he had undertaken. Busy as he was with much practice and with his hospital work he yet found time to establish a medical journal *(La Presse Médicale)* and an anatomical and pathological society, and to write numberless articles and papers, such, for instance, as Studies upon Anthracosis, on Vaccination and Contagious Ophthalmia, on the General Paralysis of Mania, on Cholera, on Fermented and Distilled Drinks, on Alcoholism, on Syphilis, on Hypnotism, on the Therapeutic Action of Digitalis, on the Action of Ergotine in the Treatment of Tuberculosis, and many other papers. Although everyone will not agree with the manner in which he treated all these subjects, yet whatever he investigated was handled in the same vigorous style, with the same absolute conviction and the same logical clearness of discussion. He was a strong partisan of his teachers and defended the ideas put forth by Broussais with an ardour and conviction which compelled the admiration even of those who did not agree with him. To the end of his life he remained bitterly opposed to the microbial theory of disease, though it must be allowed that he knew how to defend his opinions both in speech and in writing with a dialectical talent which made him no unworthy adversary. Apart from this point he was for a long time at the head of every medical scientific movement in Belgium. Despite his seventy-four years he had preserved much of the vigour of youth and his professional activity was such that his death came quite unexpectedly. The medical men of Brussels had decided to celebrate in his honour the fiftieth anniversary of his entrance into the profession, and this occasion would certainly have bound together the great majority of his medical brethren, for just as in his capacity of professor he had shown an example of absolute devotion to science, so as a physician he occupied the very first place and as a practitioner he leaves behind him the remembrance of one who was always a kindly colleague in whose hands the honour of the profession was perfectly safe. We need only further point out his devoted action in defending professional interests in the association of Brussels medical men and how at every discussion he was always attentively listened to. Among other marks of honour bestowed upon him the King of Belgium appointed him a Commander of the Order of Civil Merit.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. C. Morris Fisher, Professor of Histology in the Cooper Medical College, San Francisco.—Dr. Wiener, Extraordinary Professor of Midwifery and Gynæcology in the University of Breslau.—Dr. D. Toscani, Professor of Forensic Medicine in the University of Rome.—Dr. Simone Fubini, Professor of Materia Medica and Pharmacology in the University of Pisa.—Dr. A. J. M. de Hondt, chief medical officer of the Ostend Municipal Hospital and President of the local Medical Commission. He was Knight of the Order of Leopold and had the First-class Civic Cross. His age was sixty-five years.

---

[1] For an account of this case see THE LANCET of April 22nd, 1871, p. 543.

MANCHESTER MEDICAL SOCIETY.—At the request of the committee of this society an address was delivered on Oct. 5th by Mr. W. H. A. Jacobson, entitled "Some Remarks on Accuracy in Diagnosis or Clinical Precision—Some of the More Common Causes of Failure." Mr. G. Wright, President, was in the chair.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination in October the following candidates passed in the subjects indicated:—

PART I.

Biology.—F. W. March, Durham, and Z. Rowlands, Royal Free Hospital.

Chemistry.—W. P. Allen, Birmingham; E. M. Forsyth, Royal Free Hospital; F. P. Joscelyne, Leeds; and J. S. Ward, Sheffield.

Materia Medica and Pharmacy.—G. M. Crockett, Royal Free Hospital; H. C. Jones, St. Mary's Hospital; M. E. Martin and L. G. Simpson, Royal Free Hospital; J. S. Ward, Sheffield; and A. F. Weston, St. George's Hospital.

PART II.

Anatomy.—A. O. Ashe, King's College Hospital; J. B. Bradley, Birmingham; J. Brownrigg, Liverpool; E. J. Crew, Guy's Hospital; B. M. Dunstan, St. Thomas's Hospital; C. A. W. Egan, Dublin; L. C. Ferguson, St. Bartholomew's Hospital; V. J. Glover, Liverpool; K. Heanley, Royal Free Hospital; B. I. Rahim, King's College Hospital; J. E. Skey, Westminster Hospital; L. K. Tickner, Durham; E. D. Townroe, St. George's Hospital; J. Waters, Middlesex Hospital; J. H. Williams, London Hospital; H. F. Willington, Manchester; and E. Yoxall, Birmingham.

Physiology.—A. O. Ashe, King's College Hospital; J. C. Baggs, St. Thomas's Hospital; J. Brownrigg, Liverpool; L. C. Ferguson, St. Bartholomew's Hospital; V. J. Glover, Liverpool; D. R. T. Griffiths, Guy's Hospital; K. Heanley, Royal Free Hospital; W. J. H. Hepworth, Edinburgh and St. Mary's Hospital; G. J. W. Keigwin, London Hospital; D. A. H. Moses, St. Bartholomew's Hospital; B. I. Rahim, King's College Hospital; H. H. Serpell, St. Bartholomew's Hospital; J. E. Skey, Westminster Hospital; H. O. Sutcliffe, Cambridge; E. D. Townroe, St. George's Hospital; J. Waters, Middlesex Hospital; H. F. Willington, Manchester; and E. Yoxall, Birmingham.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Convocation held on Sept. 24th the following degrees were conferred:—

Doctor in Medicine.—Gilbert Goolor, M.B., B.S. Durh.; George Rome Hall, M.B., M.S. Durh.; Thomas George Smith Hodson, M.B. Durh.; Hugh Meyrick Meyrick-Jones, M.B., B.S. Durh.; Thomas Brice Poole, M.B., B.S. Durh.; Tom Sanderson, M.B., B.S. Durh.; George William Scott, M.B., B.S. Durh.; John Dee Shapland, M.B., B.S. Durh.; Frederick Hampson Simpson, M.B., B.S. Durh.; Charles Stewart, M.B., B.S. Durh.; Thomas Streatfeild, M.B., B.S. Durh.; William Rowland Thurnam, M.B., B.S. Durh.; Frederick Septimus Walker, M.B., B.S. Durh.; and Allan Warner, M.B. Durh.

Doctor in Medicine (Practitioners of Fifteen Years' Standing).—Thomas Wilson Aird, M.R.C.S. Eng., L.R.C.P. Lond.; Richmond Robert Allen, L.R.C.P. Edin., F.R.C.S. Irel.; Arthur Frederick Blagg, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.; William Edward Cree, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.; Edward Octavius Croft, M.R.C.S. Eng., L.R.C.P. Lond.; George William Hamilton Cumming, M.R.C.S. Eng., L.R.C.P. Edin.; Henry Peers Dimmock, M.R.C.S. Eng., L.R.C.P. Lond.; Alfred Wilson Emms, M.R.C.S. Eng., L.S.A.; George Frost, M.R.C.S. Eng., L.R.C.P. Lond.; William Henry Gimblett, L.R.C.P. Irel., L.S.A.; Benjamin John Glissan, L.R.C.P. Edin., L.F.P.S. Glasg.; Stanley Stenton Hoyland, M.R.C.S. Eng., L.S.A.; Albert Samuel Morton, M.R.C.S. Eng., L.S.A.; Thomas William Scale, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.; Henry Fraser Stokes, M.R.C.S. Eng., L.R.C.P. Lond.; Arthur Warburton, M.R.C.S. Eng., L.R.C.P. Lond.; and Thomas Wingrave, M.R.C.S. Eng., L.S.A.

Master in Surgery.—Wilfred Ernest Alderson, M.D., B.S. Durh.

Bachelor in Medicine.—Arthur Samuel Arthur and Joseph Ellis Baker, College of Medicine, Newcastle-upon-Tyne; Gerald Burton Brown, L.S.A., Guy's Hospital; Frank Anthony Cooke, Henry Coxon Coxon, and Leopold Stanley Davison, College of Medicine, Newcastle-upon-Tyne; Howard Henry Congreve Dent, M.R.C.S. Eng., L.R.C.P. Lond., Mason College, Birmingham; Charles Edward Fenn, King's College, London; Henry Adamson Fielden and John Maxwell Gover, College of Medicine, Newcastle-upon-Tyne; Herbert George Harris, M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital; Margaret Joyce, London School of Medicine for Women; George Whitson Middlemiss, College of Medicine, Newcastle-upon-Tyne; Robert Fletcher Moorshead, University College, Bristol; William Byron Milbanke, College of Medicine, Newcastle-upon-Tyne; Claudia Anita Prout Rowse, London School of Medicine for Women; Grace Harwood Stewart, London School of Medicine for Women; George Grey Turner, College of Medicine, Newcastle-upon-Tyne; Leslie Herbert Walsh, M.R.C.S. Eng., L.R.C.P. Lond., King's College, London; and William Henry Warwick, College of Medicine, Newcastle-upon-Tyne.

Bachelor in Surgery.—Arthur Samuel Arthur and Joseph Ellis Baker, College of Medicine, Newcastle-upon-Tyne; Gerald Burton Brown, L.S.A., Guy's Hospital; Frank Anthony Cooke, Henry Coxon Coxon, Leopold Stanley Davison, Henry Adamson Fielden, and John Maxwell Gover, College of Medicine, Newcastle-upon-Tyne; Herbert George Harris, M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital; Margaret Joyce, London School of Medicine for Women; Alfred Phillips Lloyd, M.B., and George Whitson Middlemiss, College of Medicine, Newcastle-upon-Tyne; Robert Fletcher Moorshead, University College, Bristol; William Byron Milbanke, College of Medicine, Newcastle-upon-Tyne; Grace Harwood Stewart, London School of Medicine for Women; George Grey Turner, College of Medicine, Newcastle-upon-Tyne; and Leslie Herbert Walsh, M.R.C.S. Eng., L.R.C.P. Lond., King's College, London.

Bachelor in Hygiene.—John Wreford, M.B. Durh., M.R.C.S. Eng., L.R.C.P. Lond.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Alfred Goldscheider, *privat-docent* of Internal Medicine, and Dr. Karl Horstmann, *privat-docent* of Ophthalmology, have been appointed Extraordinary Professors.—*Innsbruck:* Dr. W. Türk, Extraordinary Professor of Histology and Embryology, has been appointed Ordinary Professor.—*Lemberg:* Dr. Anton Mars of Cracow has been appointed Professor of Midwifery and Gynæcology and Dr. J. Wiczkowski has qualified as *privat-docent* of Internal Medicine.—*Naples:* Dr. Vincenzo de Meis has qualified as *privat-docent* of Medical Pathology.—*Prague (Bohemian University):* Dr. J. Hnâtek has qualified as *privat-docent* of Internal Medicine.—*Rio de Janeiro:* Dr. Miguel de Oliveira Couto has been appointed Assistant Professor of Pathology and Clinical Medicine.

UNIVERSITY COLLEGE, BRISTOL.—Professor R. Fanshawe delivered the opening lecture of the winter session at University College, Bristol, on Oct. 3rd. The subject was the English and Roman Empires. Professor Lloyd Morgan presided over a large audience.

CHORLTON UNION COTTAGE HOMES.—The cottage homes and schools at Styal built by the Chorlton Guardians were opened on Oct. 4th by the Marquis of Lorne. They are situated in a pleasant part of the neighbouring county of Chester and, so far as situation goes, are free from the suggestion of workhouse association. There is a probational lodge where new-comers will undergo a fortnight's quarantine to guard against the importation of infectious disease. The cottages, of which there are 17, are of red brick with terra-cotta facings and separated from each other by gardens where the children will be taught the cultivation of vegetables and flowers. Each cottage contains a day-room, a dining-room, offices, a bathroom, and bedrooms, and is in charge of foster-parents carefully chosen. Accommodation is provided for 310 children; there is a small Kindergarten school for the little ones, while for the older children there is a school planned to accommodate 500. There are workshops for the boys, where plumbing, bootmaking, carpentry, &c., will be taught, and swimming-baths, all good and useful arrangements, but all very different from the associations of family life, which it is impossible to produce wholesale, though the guardians have tried to create a passable imitation. The girls will be taught household work and domestic economy. There is also an isolation hospital with sixteen beds. The buildings and ground about them cover fifty acres. The whole is lighted by electricity. The cost to the guardians has been a little more than £50,000.

THE ABERNETHIAN SOCIETY OF ST. BARTHOLOMEW'S HOSPITAL.—The annual opening address of the above society was given at the hospital on Oct. 6th by Sir Thomas Smith. There was an enthusiastic audience of nearly 500 people. Sir Thomas Smith described his earliest impressions when he entered the hospital some fifty years ago, and from these comparatively remote times he traced the progress which had taken place in its administration, practice, and teaching, and he dwelt upon the gradual improvement in the manners and morals of its students. The first conclusion he drew as a student was that the good old days had passed away and that his "lot had fallen on evil times." This was the spirit which overshadowed the whole hospital and continued up to the time of Humphry, who was wont to exclaim, "Where are the giants of the past?" But this was not the right way to approach surgery. Too much stress was laid upon the dicta of their great predecessors and it must always be borne in mind that surgery has no fixed principles. Sir Thomas Smith spoke, too, of the great changes which had taken place in the curriculum required for examinations. In his time two and a half years was sufficient, now the minimum for any diploma was five years. He welcomed the emancipation of women, by virtue of which movement the nursing of the sick was now done by the educated and refined, to the benefit of patients and all concerned. The introduction of chloroform as a general anæsthetic and of antiseptic methods in surgery was also touched upon. After the address Sir Dyce Duckworth proposed a vote of thanks to Sir Thomas Smith, which was seconded by Mr. Bowlby, and cordially responded to by those present.

INFECTIOUS DISEASES HOSPITAL FOR NEWPORT (MON.).—On Oct. 7th a Local Government Board inquiry was held into the proposal of the Newport Corporation to borrow £7500 for the purpose of extending the Infectious Diseases Hospital.

A NEW COTTAGE HOSPITAL.—Mr. G. Wills has offered to endow a cottage hospital for Moreton Hampstead, Devon. A committee formulated a plan which the Hon. W.F.D. Smith so much approved of that he has proposed to give a site and erect the building.

THE STUDY OF THE SPANISH LANGUAGE.—With a view of helping the young men and women of England to obtain a commercial education fitting them to compete on equal terms with those of other nations, Sir Isaac Pitman and Sons, Ltd., announce another language weekly, in addition to their already popular French and German weeklies. The title of the new venture will be "Pitman's Popular Spanish Instructor," to be published weekly at 1½*d*. The idea is to thoroughly popularise the study of the Spanish language by furnishing from week to week useful matter for both the beginner and the advanced student in the form of business interviews, correspondence, commercial terms, &c.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—This society met for the first time this session on Oct. 7th, when the President, Dr. G. S. Middleton, gave a demonstration of cases. He showed (1) a case of Paralysis illustrating the difficulty of diagnosis between functional and organic disease; (2) a slightly marked case of Myxœdema in which the diagnosis had at first been missed, the patient having been treated for Bright's disease; (3) a case of Progressive Muscular Atrophy accompanied with Bulbar Paralysis; (4) a case of Paralysis Agitans affecting chiefly the left side and sparing the head; (5) a case of Disseminated Sclerosis in an Early Stage; and (6) a well-marked instance of Dermography.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The School of Surgery has resumed work for the Winter Session. The following is a list of the prize-winners:—Barker's Anatomical Prize: Miss K. F. Lynn, £26 5*s*.; and J. S. P. Stewart, £15 15*s*. Carmichael Scholarship: C. R. Boyce, £15. Mayne Scholarship: D. Hadden, £15. Gold and Silver Medals in Operative Surgery: G. W. Little, gold medal; T. G. N. Stokes, silver medal; and S. R. Godkin, certificate of merit. Descriptive Anatomy: Junior—A. Charles, first prize (£3) and medal; and R. H. Oulton, second prize (£1) and certificate. Senior—J. P. Byrne, first prize (£3) and medal; and C. R. Boyce, second prize (£1) and certificate. Practical Anatomy: First Year—R. H. Oulton, first prize (£3) and medal; and T. C. Fitzgerald, second prize (£1) and certificates. Second Year—C. R. Boyce, first prize (£3) and medal; and J. F. Peart, second prize (£1) and certificate. Third Year—J. S. P. Stewart, first prize (£3) and medal; and T. C. Fitzgerald, second prize (£1) and certificate. Practice of Medicine: G. W. Little, first prize (£3) and medal; and J. S. P. Stewart, second prize (£1) and certificate. Surgery: D. A. Fitzgerald, first prize (£3) and medal; and H. H. Swanzy, second prize (£1) and certificate. Midwifery: D. A. Fitzgerald, first prize (£3) and medal; and M. Gavin, second prize (£1) and certificate. Physiology: J. F. Peart, first prize (£3) and medal; and J. P. Byrne, second prize (£1) and certificate. Chemistry: Miss M. J. Shire, first prize (£3) and medal; and L. C. E. Murphy and W. J. O'Doherty (equal), second prize (£1) and certificate. Pathology: J. S. P. Stewart, first prize (£3) and medal; and S. R. Godkin, second prize (£1) and certificate. Physics: Miss M. J. Shire, first prize (£3) and medal; and W. B. A. Moore, second prize (£1) and certificate. Practical Histology: J. P. Byrne, first prize (£3) and medal; and R. H. Oulton, second prize (£1) and certificate. Practical Chemistry: W. Delaney and Miss M. J. Shire (equal), first prize (£3) and medal. Public Health and Forensic Medicine: D. A. Fitzgerald, first prize (£3) and medal; and Mrs. H. L. Hennessy, second prize (£1) and certificate. Materia Medica: J. Levis, first prize (£3) and medal; and W. R. Meredith, second prize (£1) and certificate. Practical Pharmacy: E. Evatt, first prize (£3) and medal; and Miss M. J. Shire, second prize (£1) and certificate. Biology: Miss M. J. Shire, first prize (£3) and medal; and R. E. Humphrey, second prize (£1) and certificate. A supplemental entrance examination will be held on Nov. 1st.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the monthly meeting of the College, held on Oct. 7th, William John Thompson, M.D.Dub., was admitted as Member.

FREEMASONRY.—*Rahere Lodge, No. 2546:* A meeting of this lodge was held at Frascati's Restaurant, W., on Oct. 11th, W. Bro. Burns, P.P.G.D. Surrey, being in the chair. Bros. Carnall and Hoyland were admitted to the third degree. Bros. Briggs, Mackintosh, Heath, Keats, Brewerton, and Burrows were admitted to the second degree and Mr. Coventon was elected a member of the Lodge. Two communications were read from the United Grand Lodge and the Deputy Master of the Sancta Maria Lodge, No. 2682, was elected an honorary member. The Brethren afterwards dined together.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—The following gentlemen have been elected officers for the ensuing year 1898-99:—President: Dr. Middlemas Hunt (Liverpool). Vice-presidents: Dr. Davison (Bournemouth), Mr. John Bark (Liverpool), and Mr. Wyatt Wingrave. Council: Dr. Dundas Grant, Dr. W. Hill, Dr. Greville MacDonald, Dr. Abercrombie, Mr. Percy Jakins, Dr. H. Woods (Dublin), and Dr. A. B. Kelly (Glasgow). Treasurer: Dr. McNeil Whistler. Honorary secretaries: Mr. St. George Reid and Dr. Furniss Potter.

PRESENTATIONS TO MEDICAL MEN.—Dr. Francis J. Waring, of Eaton-road, Hove, honorary physician to the Police Seaside Home, Hove, has been presented with a black marble timepiece with Corinthian pillars of black bronze, with inscription, from many of the convalescents at the home, to which he has given his voluntary services during the past eight and a half years. Inspector Foot, C Division, Metropolitan Police, came from London to make the presentation in the presence of the policemen now resident in the home, Colonel Philips (chairman of committee), Mr. W. Berners Wilson, Miss Griffen (hon. lady superintendent), and others. Inspector Foot, in presenting the timepiece, said that the gift was in no way proportionate to the gratitude which hundreds of convalescent policemen felt for Dr. Waring's kind and efficient medical treatment, but they hoped he would accept it as a slight token of their deep appreciation of his valued and unwearied labours on their behalf. The inscription on the clock was as follows: "Presented to Francis J. Waring, Esq., M.D., M.R.C.S., by many of the visitors to the Convalescent Police Seaside Home, Hove, in recognition of his unwearied and voluntary services to them and their comrades for nearly nine years. September. 1898."—On Sept. 27th, at the Great Western Railway Station, Cardiff, after the annual distribution of certificates and medals for those employés who had successfully passed the examination for "first aid" in connexion with the St. John Ambulance Association, Mr. William Taylor, M.D., L.R.C.P. Edin., M.R.C.S. Eng., was presented with a silver cigarette case engraved with his initials in appreciation of his services as honorary lecturer of the class. —On Sept. 26th, in the council chamber, Macduff, a large number of the public assembled for the purpose of bidding farewell to Mr. A. B. Lyon, M.B. Aberd., on his leaving Macduff. Provost Bisset presided, and presented to him, on behalf of the subscribers, a gold watch and a purse of sovereigns, speaking in eulogistic terms of Mr. Lyon's personal character and ability.

BOOKS, ETC., RECEIVED.

BAILLIÈRE ET FILS, Paris.
Chirurgie des Voies Urinaires. Par Dr. E. Chevalier. 1899.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BLUMFELD, J., M.D., B.C. Cantab., has been appointed Surgeon at the Chelsea, Brompton, and Belgrave Dispensary, S.W.

BULLMORE, CHARLES CECIL, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed *pro tem.* Medical Officer for Mylor by the Falmouth Board of Guardians, vice E. Head-Moore.

BUTTERWORTH, J. J., M.B., Ch.B. Vict., has been appointed a Second Assistant Medical Officer for the Monsall Hospital.

CHANCE, A., L.R.C.P., F.R.C.S. Irel., has been appointed Consulting Surgeon for the St. Michael's Hospital, Kingstown.

CROWLEY, RALPH H., M.D. Lond., has been appointed Honorary Physician for the Bradford Royal Infirmary.

DE JERSEY, W. B., M.B. Cantab., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed an Honorary Assistant Medical Officer for the Royal Surrey County Hospital, vice J. P. A. Gabb.

DOWDEN, J. W., M.B., F.R.C.S. Edin., has been appointed a Medical Officer in the University Surgical Wards, Royal Infirmary, Edinburgh.

ELDER, G., M.D., F.R.C.P. Edin., has been re-appointed a University Clinical Tutor, Royal Infirmary, Edinburgh.

FAIRWEATHER, W. E., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Resident Medical Officer for the Guest Hospital, Dudley.

FORDYCE, W., M.D. Edin., has been re-appointed a Medical Officer in the Gynæcological Wards, Royal Infirmary, Edinburgh.

FOWLER, J. S., M.B., M.R.C.P. Edin., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed a Medical Officer in the Extra-mural Medical Wards, Royal Infirmary, Edinburgh.

GENGE, G. GILBERT, M.D., B.S. Lond., D.P.H. Camb., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Resident Medical Officer for the Croydon General Hospital.

GILL, J. S., L.R.C.P., L.R.C.S., Edin., L.F.P.S. Glasg., has been appointed a Medical Officer for the Clonavaddy District, Dungannon Union.

HEDLEY, A. S., M.B., B.S. Durh., has been appointed Medical Officer for the Workhouse and the Rothbury East Sanitary District of the Rothbury Union.

HICK, HENRY, L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Medical Officer of Health for the New Romney Borough.

HONEYBURNE, R., M.D. Lond., M.R.C.S. Eng., has been appointed an Honorary Medical Officer for the Bradford Infirmary, vice J. Kerr.

HOWARTH, WILLIAM J., M.D., D.P.H. Vict., has been appointed Medical Officer of Health for the County Borough of Derby, vice Wm. Iliffe, deceased.

LACKIE, J. L., M.D., F.R.C.P. Edin., has been appointed a Medical Officer in the Gynæcological Wards, Royal Infirmary, Edinburgh.

MARSTON, F. E., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Medical Officer for the Welshpool Sanitary District of the Forden Union.

MILLER, G. V., M.B., C.M. Edin., has been appointed Eye, Ear, and Throat Specialist, North Riding Infirmary.

ORME, W. BRYCE, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Principal Medical Officer to the Government Hospital, Port Said, Egypt, vice F. R. S. Milton.

POGSON, BUCKLEY, M.D., has been appointed Visiting Medical Officer for the Protestant Dissenting Charity Schools, Birmingham.

PURVES, R. B., M.B., C.M. Edin., has been appointed a Medical Officer to the Extra-mural Surgical Wards, Royal Infirmary, Edinburgh.

RAINY, H., M.B., C.M., F.R.C.P. Edin., has been re-appointed a University Clinical Tutor, Royal Infirmary, Edinburgh.

ROBERTS, KILHAM, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer of Health for the Ampthill Rural District Council.

SCOTT, J., M.B., D.P.H. Edin., has been appointed a Medical Officer to the Extra-mural Surgical Wards, Royal Infirmary, Edinburgh.

SKIRVING, A. A. S., M.B., F.R.C.S. Edin., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed a Medical Officer to the Extra-mural Surgical Wards, Royal Infirmary, Edinburgh.

WALTER, R. H., M.B., C.M. Edin., has been appointed Medical Officer for the Sixth Sanitary District of the Yeovil Union.

WATERSTON, D., M.B., C.M. Edin., has been appointed a Medical Officer to the Extra-mural Surgical Wards, Royal Infirmary, Edinburgh.

WELSH, D. A., B.Sc., M.D. Edin., has been re-appointed a University Clinical Tutor, Royal Infirmary, Edinburgh.

WHITAKER, E. T., M.B., Ch.M., B.Sc., Edin., D.P.H. Camb., F.C.S., has been appointed Medical Officer of Health for the Ellesmere Urban and Rural District Councils, vice G. J. Glasson, resigned.

WOODHEAD, T. FIELDING, M.R.C.S., L.R.C.P., has been appointed Certifying Surgeon to Factories for the Meltham Urban District, vice T. A. Haigh, resigned.

YULE, G. P., M.B., M.S. Edin., has been appointed a Third Medical Assistant Officer for the Monsall Hospital.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

BATH GENERAL OR ROYAL MINERAL WATER HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum with board and apartments in the Hospital.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary £150 per annum, with an allowance of £30 per annum for cab hire, and furnished rooms, fire, lights, and attendance.

BOROUGH OF RICHMOND (Surrey) and HESTON AND ISLEWORTH URBAN DISTRICT JOINT ISOLATION HOSPITAL COMMITTEE.—Resident Medical Officer at the new Isolation Hospital at Mogden, near Kneller Hall, Twickenham, unmarried. Salary £100 per annum, with furnished apartments in the Hospital, rations, and washing. Applications to the Clerk to the Joint Committee, 172, High-street, Hounslow, Middlesex.

CARDIFF INFIRMARY.—Assistant House Physician for six months. Salary at the rate of £50 per annum, with board, washing, and apartments.

COUNTY BOROUGH OF BURY.—Medical Officer of Health for the Borough and Urban Sanitary District of Bury. Salary £300 per annum, with actual disbursements. Applications to the Town Clerk, Corporation Offices, Bury.

DUNDEE ROYAL LUNATIC ASYLUM.—Two Medical Assistants. Salary £100 each, with board and lodging.

GRIMSBY AND DISTRICT HOSPITAL, Great Grimsby.—Resident House Surgeon. Salary £80 per annum, board, lodging, and washing.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL, Hastings.—Assistant House Surgeon for six months. Gratuity of £10, with residence, board, and laundry.

HERTFORDSHIRE COUNTY ASYLUM at Hill-end, near St. Albans.—Medical Superintendent. Salary to commence at £500 a year. Certain arrangements as to accommodation until the asylum is completed will be made, and also as to furnished residence, &c., in addition to the salary. Applications to the Clerk to the Hertfordshire County Council, Hertford.

HOSPITAL FOR WOMEN, Soho-square, London.—House Physician for six months. Salary £30 for that period.

INFIRMARY OF THE CITY OF LONDON UNION.—Assistant Medical Officer at the Infirmary, Bow-road. Single or widower without children. Salary £150 per annum, with furnished apartments at the Infirmary, rations, and washing, subject to statutory deductions. Applications to the Clerk to the Guardians, 61, Bartholomew-close, E.C.

KENT AND CANTERBURY HOSPITAL, Canterbury.—Assistant House Surgeon. Unmarried. Salary £50 a year, with board and lodging.

LEICESTER INFIRMARY.—House Surgeon. Salary £120 the first year, rising £10 per annum until the third year. Board, apartments, and washing provided.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Resident Medical Officer for one year. Salary 100 guineas per annum, with board, lodging, and washing.

LONDON THROAT HOSPITAL, 204, Great Portland-street.—House Surgeon (non-resident) for six months. Salary at the rate of £25 per annum.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Resident Medical Officer and Assistant Resident Medical Officer for six months. Salary at the rate of £50 per annum attaches to the senior post.

ROTHERHAM HOSPITAL AND DISPENSARY.—Resident House Surgeon for three years. Salary £105 per annum, board and washing.

ROYAL FREE HOSPITAL, Gray's-inn-road, London.—House Surgeon for six months. Board, &c., provided.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road, London.—Resident Medical Officer for twelve months. Salary £70 a year, with board, lodging, and washing.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London.—Resident Medical Officer for six months. Salary at the rate of £100 per annum, with furnished apartments, board, and washing.

ROYAL ORTHOPÆDIC HOSPITAL, 297, Oxford-street, and 15, Hanover-square, London.—House Surgeon and Anæsthetist for six months, unmarried. Salary at the rate of £100 per annum with residence and partial board.

Digitized by Google

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL, Portsmouth.—Assistant House Surgeon for six months. Board and residence and an honorarium of £15 15s.

ROYAL SOUTH LONDON DISPENSARY, St. George's-cross, S.E.—Dispenser. Salary 30s. per week and use of furnished apartments, with coals, gas, and water.

SCHOOL BOARD FOR LONDON.—Qualified Medical Practitioners to give Lectures on First Aid and Home Nursing to the pupils of the Evening Continuation Schools. Applications to the School Board for London, Victoria Embankment, W.C.

SOUTH LAMBETH, STOCKWELL, AND NORTH BRIXTON DISPENSARY, Wilkinson-street, Albert-square, Clapham-road, S.W.—Vacancy on the Visiting Medical Staff.

TORBAY HOSPITAL PROVIDENT DISPENSARY AND EYE INFIRMARY, Torquay.—House Surgeon. Salary £80 and board, lodging, washing, and attendance (wines, spirits, and beer excepted).

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for one year. Salary £75 per annum, with board, residence, &c.

Births, Marriages, and Deaths.

BIRTHS.

ATTLEE.—On Oct. 8th, at 58, Brook-street, London, W., the wife of John Attlee, M.D., of a daughter.

BOGLE.—On Oct. 4th, at New Ferry Park, near Birkenhead, the wife of James Linton Bogle, M.D., of a son.

BRIGHTMAN.—On Oct. 4th, at Aspley House, Broadstairs, the wife of Frank Brightman, M.R.C.S., L.R.C.P., of a daughter.

BROOKE.—On Oct. 3rd, at Buxton House, West Bridgford, Notts, the wife of Frederick Brooke, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

CHEYNE.—On Oct. 12th, at 75, Harley-street, W., the wife of W. Watson Cheyne, F.R.C.S., F.R.S., of a son.

HOLCROFT.—On Oct. 7th, at Tramore, St. Leonards-on-Sea, the wife of Edgar Holcroft, M.A., M.B., of a daughter.

HUTCHINSON.—On Oct. 6th, at Loneside, Haslemere, the wife of Roger J. Hutchinson, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

BUIST—HUTCHISON.—At the cathedral church of St. Mary, Edinburgh, on Oct. 11th, 1898, by the Rev. Hugh J. Lawlor, D.D., Professor of Ecclesiastical History in the University of Dublin, John Brown Buist, M.D., to Helen, younger daughter of the late Henry Hutchison, 4, Grosvenor-street, Edinburgh.

CANDLER—WHISTLER.—On Oct. 4th, at Stockland Church, near Bridgwater, George Candler, B.A. Cantab., M.R.C.S., L.R.C.P., son of John Candler, M.R.C.S., of Harleston, Norfolk, to Edith Benedicta, daughter of the late Rev. R. F. Whistler, of Elton, Peterborough.

DEANESLY—MARSTON.—On Oct. 5th, at St. Peter's Collegiate Church, Wolverhampton, Edward Deanesly, M.D., B.Sc., F.R.C.S., to Ida Margaret, second daughter of John Marston, J.P., The Oaks, Wolverhampton.

MACMULLAN—THOMAS.—On Oct. 6th, at St. James's, Piccadilly, James Neil Macmullan, L.R.C.P. & S.E., L.F.P.S.G., of Drybrook, Glos., to Fanny Maude, eldest daughter of Richard Thomas, of Penarth.

STEDMAN—HETHERINGTON.—On Oct. 6th, at St. Peter's, Hull, Bernard Stedman, M.D. Lond., of Leighton Buzzard, to Clara Edith Hetherington.

TURNER—BARRY.—On Oct. 5th, at St. Stephen's, South Dulwich, John Sidney Turner, M.R.C.S., F.L.S., of Stanton, Anerley, S.E., to Emily Jane, only daughter of the late Dr. John Boyle Barry of Calcutta.

DEATHS.

BLACKFORD.—On Oct. 1st, at Cannock, John Cromwell Blackford, M.R.C.S., L.S.A., aged 76.

GOLDTHORP.—On Oct. 8th, at her residence, Howard House, Upper Norwood, in her 86th year, Laetitia Goldthorp, eldest daughter of the late William Browne, Esq., of Stanton's Wharf, Bermondsey, some time widow of the late Samuel Radcliffe, Esq., M.D., of Leeds, and afterwards widow of the late Robert Goldthorp, Esq., of Leeds and Norwood.

JACKMAN.—On Oct. 11th, at 11, Stoke Newington-road, N., Sarah, wife of T. S. H. Jackman, L.R.C.P. Lond., M.R.C.S. Eng.

NEWCOMBE.—On Oct. 2nd, at Woodhall Spa, Lincoln, Henry Newcombe, F.R.C.S.E., of Dalrymple-crescent, Edinburgh.

REW.—On Oct. 6th, at Western-road, Bexhill, James Rew, M.R.C.S., L.S.A.

WILKINS.—On Oct. 5th, at Brixton-road, Gilbert Hamilton Wilkins, M.D., aged 48.

N.B.—A fee of 5s. is charged for the insertion of Notice of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat Hospital (2 P.M.).

TUESDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.), Royal Ear Hospital (3 P.M.).

WEDNESDAY (19th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

THURSDAY (20th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.).

FRIDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (22nd).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (18th). — PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. F. W. Andrewes: Follicular Enteritis due to Streptococci and Bacillus Enteritidis Sporogenes.—Mr. S. G. Shattock: Acromegalic Skull.—Dr. W. S. L. Barlow: Carcinoma (?) arising in an Accessory Thyroid Gland.—Mr. H. B. Robinson: Button Cyst of the Breast.—Dr. H. Walsham: On the occurrence of Bony and Cartilaginous Nodules in the Tonsil.—Mr. P. de Santi: Multiple Primary Sarcomata of the Scalp of nineteen years' duration, Removal, Recurrence in the Lungs.

CHELSEA CLINICAL SOCIETY (Holy Trinity Parish Hall, Pavilion-road, S.W.).—8.30 P.M. Dr. J. F. Palmer (President): On certain Undefined Factors in the Spread of Disease (Opening Address).

WEDNESDAY (19th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Papers:—Mr. J. N. Coombe: The Reproduction of Diatoms.—Mr. F. W. Millett: Report on the Recent Foraminifera of the Malay Archipelago (Part III.).

NORTH-WEST LONDON CLINICAL SOCIETY (North-West London Hospital).—8.30 P.M. Monthly Demonstration of Clinical Cases.

THURSDAY (20th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Edgware-road).—8.30 P.M. Clinical Meeting. The following Cases will be shown: Dr. A. P. Luff: A Case of Great Enlargement of the Spleen.—Mr. S. Collier: (1) Congenital Dislocation of Patella; (2) A Case for Diagnosis.—Mr. J. Clarke: Cases of Spinal Caries.—Dr. J. Taylor: A Case of Paralysis.—Dr. L. Guthrie: Left Hemiplegia associated with Atrophy of Right Optic Nerve.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Cases and Card Specimens. 8.30 P.M. Papers:—Mr. J. F. Bullar and Mr. C. D. Marshall: Tumours of the Optic Nerve.—Capt. Herbert: The Tension of the Eye in Irido-Cyclitis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (17th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. H. Tilley: Demonstration of Selected Cases (Ear, Throat, Nose).

THE SANITARY INSTITUTE, (Parkes Museum, Margaret-street, W.).—8 P.M. Sir Douglas Galton (Chairman of Council): Introductory Address to Twenty-sixth Course of Lectures and Demonstrations in Sanitary Science for Sanitary Officers and Students.

TUESDAY (18th).—ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Sir Dyce Duckworth: Harveian Oration.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street).—4 P.M. Dr. H. Campbell: On the Motor Tract, with Cases of the Different Types of Paralysis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, W.C.).—3.30 P.M. Dr. Buzzard: Peripheral Neuritis.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. P. Abraham: Pityriasis Rosea and Tinea Versicolor.—Bethlem Hospital, 2 P.M., Dr. Craig: Melancholia and Hypochondriasis.

WEDNESDAY (19th). — LONDON POST-GRADUATE COSURE. — Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: Construction of Dwelling Houses.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Mitchell Bruce: Aneurysm of the Aorta.

Digitized by Google

THURSDAY (20th). — LONDON POST-GRADUATE COURSE. — Central London Sick Asylum Cleveland-st., W., 5.30 P.M., Mr. F. Taylor: Clinical Lecture.
THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Batten: Demonstration of Selected Cases.
CHARING-CROSS HOSPITAL.—4 P.M. Mr. Waterhouse: Demonstration of Surgical Cases. (Post-Graduate Class.)
LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical Demonstration to Senior Students.
FRIDAY (21st).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Examination of Air, Soil, and Water.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. S. Taylor: Surface Anatomy of the Lower Extremity.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

NICOTIANA.

SINCE James I. began the attack with his famous "Counterblast" there has been no lack of fulmination against users of the plant which Sir Walter Raleigh describes as "ye herb called by ye natives yppowoc," and yet not only do smokers still abound but they actually seem to be becoming more and more numerous every day. Anti-tobacconists are doubtless for the most part actuated by praiseworthy motives, although in some cases they may be seeking to "compound for sins they have a mind to," as Butler has it, but it is nevertheless a fact that moderate indulgence in sound tobacco has never been shown to be injurious to grown people. But if the nicotian citadel has proved itself impregnable, there are sundry outworks, so to speak, where a measure of success, if not absolute victory, has been claimed by the stormers in spite of strenuous denials on the part of the besieged. According to Dr. Etienne of Nancy the mortality prevailing among the children of women who are employed in manufacturing tobacco is more than double that of the infantile population in general, amounting to as much as 100 per cent. when the mothers resume work immediately after their confinement and sinking to about normal when they refrain from re-entering the factory until their infants have been duly weaned. The poisonous character of a woman's milk while she is in the habit of manipulating tobacco is thus, in Dr. Etienne's opinion, conclusively proved, but in the opinion of M. Darquier, who thirty years ago founded a *crèche* in a tobacco factory at Toulouse, the conclusion is by no means justified. Having successfully administered his *crèche* ever since its foundation the nicotian advocate writes to the *Revue Scientifique* in order to protest against the Nancy practitioner's assumptions. According to M. Darquier, "tobacco exercises no injurious effect whatever on the milk of the workwomen who are engaged in manufacturing it," and he is able to adduce figures which seem to sustain his argument. Often since the *crèche* was started there have been as many as 1800 infants accommodated in a single year, but instead of the excessive mortality given by Dr. Etienne the average death-rate for the whole period is only 17·94 per cent. It is true that some of the children were aged eighteen months and upwards on admission, but when these are eliminated from the calculation the results are still favourable to tobacco, as will be seen by the following statement: death-rate among infants nursed in the *crèche* by their mothers, 22·10 per cent.; death-rate among infants brought up in the *crèche* by hand, 41 per cent. Apparently M. Darquier has most successfully defended his outwork, but no doubt his antagonist will resume the assault.

A FRENCH VIEW OF THE VACCINATION ACT.

UNDER the heading of "La Vaccination en Angleterre" the *Revue Scientifique* of Oct. 8th has an article in which the following remarks occur:—

> "We all know that according to a recent law which has been passed owing to the efforts of the antivaccinationists it is from henceforth legal for anyone not only to refrain from having himself vaccinated, but also to refrain from having his children vaccinated. Whoever can prove before a magistrate that he has a "conscientious objection" as to vaccinating himself or his children can escape vaccination. We do not quite see how the magistrate is to weigh the value of the conscientious objections but that does not matter. ..... What the anti-vaccinationists want to do is to perform an experiment which no medical man would have dared to suggest and the expenses of which they will have to pay. ..... So much the worse for the ignorant, for those who do not wish to learn, ... their experiment will only fortify the partisans of vaccination in their opinion."

THE HISTORY OF PULSE COUNTING.

IN the course of an address on the nerves of the heart published in the *Deutsche Medicinische Wochenschrift* of August 4th Professor von Leyden mentioned, on the authority of Professor Pagel, that John Floyer (1649–1734) is spoken of as the first who employed a watch in practice for determining the pulse-rate, although William Harvey (1578–1657) had already used a watch for a similar purpose. In the issue of that journal of Oct. 6th Professor C. Binz draws attention to an earlier originator of the same idea—namely, the German cardinal Nikolaus Krebs, of Cues (pronounced Cuhs) on the Moselle, well known in the history of the fifteenth century as Cusa or Cusanus. Of course, timekeepers suitable for pulse counting did not exist in Cusa's day, as the earliest form of the watch was the "Nuremberg egg" invented by Peter Henlein, who died in 1542. The cardinal lived from 1401 to 1464. In his dialogue "De Staticis Experimentis," which he wrote in 1450, he recommended the use of the balance in scientific experimentation, and Professor Binz gives a lengthy quotation taken from a copy of the treatise bound up with an edition of Vitruvius "De Architectura," published at Strassburg in 1543. The following is an extract, immediately after which comes a suggestion that the respirations in health and in illness might be compared in a similar manner.

> "Nonne putas, si aquam ex stricto foramine clepsydrae in pelvim permitteres, quousque sani adolescentis pulsum centies sentires et similiter ageres in adolescenti infirmo, inter aquas illas ponderis cadere differentias? Ex pondere igitur aquarum ad diversitatem pulsuum in juvene, sene, sano et infirmo perveniretur, et ita ad morbi veriorem notitiam, cum aliud pondus in una infirmitate, aliud in alia necessario eveniret. Unde perfectius fieret judicium ex experimentali pulsuum tali differentia et pondere urinae, quam tactu venae et colore urinae tantum."

Floyer practised at Lichfield and was knighted in or before 1686. The account of him in the "National Dictionary of Biography" is by Dr. J. F. Payne, who says: "Floyer was the first to make regular observations upon the rate of the pulse, counting the number of beats in a minute by the watch. Before his time, though other points connected with the pulse had been carefully studied, this had been neglected. The pulse-watch was merely a watch constructed to go for exactly one minute. ..... Floyer did good service also by his advocacy of cold bathing in a work published under different titles in several editions. ..... The work on Asthma is also very noteworthy, not only as containing excellent clinical observations, but as giving the first account, derived from dissection, of the change in the lungs now called emphysema."

THE AMERICAN ARMY IN CUBA.

AN editorial article in the *Philadelphia Polyclinic* of Sept. 10th says: "We are among those who trust that the request of Surgeon-General Sternberg for an investigation will be granted and that the investigation will be thorough and judicial. We have never doubted, and we do not doubt now, that its result will be creditable to the medical corps of the United States Army, from the Surgeon-General to the youngest and most inexperienced of the surgeons appointed from civil life. Accumulating evidence seems to show that failure upon the part of camp officers to heed the warnings and obey the suggestions of the regimental surgeons is responsible for the epidemics of typhoid fever, and that the outbreak of yellow fever was due to General Shafter's brutal and ignorant course, seemingly prompted entirely by a spirit of childish opposition, in disregarding the warnings and the advice of Dr. Senn, Dr. Wood, and his own chief medical officer."

"WHAT IS A *BONÂ-FIDE* STUDENT?"

To the Editors of THE LANCET.

SIRS,—Your reply to my letter under the above heading in THE LANCET of Oct. 8th, if it correctly interprets the meaning of the General Medical Council, practically closes the door of the profession to my employé and to all like him who, having no means, are deprived of the power to make use of the knowledge they have gained to earn sufficient money to see them through their final. I do not think I am exaggerating when I say that hundreds of medical students complete their curriculum and do not feel themselves equal to pass the final, and when they do face it are often referred. What are these men to do if they have no money? They are no longer *bonâ-fide* students if your opinion is correct, and consequently not eligible for pupil assistantships. If medical men employ them, even in that capacity in which they have proved themselves to be efficient, the former are liable to be censured by the General Medical Council, though it would appear that *bonâ-fide* students of less experience and unproved efficiency could be legitimately so employed. If I am not trespassing too much on your space I shall be glad if you will give me your opinion as to whether any further employment in medical practice beyond bookkeeping and dispensing can be found for men in the position of my employé.

I am, Sirs, yours faithfully,

Oct. 10th, 1898. L.R.C.P.

DURHAM UNIVERSITY AND THE M.D. FOR PRACTITIONERS.

To the Editors of THE LANCET.

SIRS,—As I have just had the good fortune to obtain the above degree, and as Durham is the *only* university in England which kindly and liberally widens her portals so as to reward the general practitioner after he has attained the age of forty years, I write with your kind permission to shed a little light upon the matter for the benefit of others who wish to graduate, as there are some points which do not seem to be well understood. First, *either* the Latin or the Professional may be taken separately or first. To one who has forgotten the former I would say, take it up first and *alone*, so as to be free for the professional subjects afterwards. The time allowed for the latter will of course depend upon the abilities and opportunities of the candidate, say three or four hours' reading daily for six or twelve months. A list of books is to be obtained in the University Calendar, which will be forwarded by the kind and courteous secretary, Dr. Howden. Get the latest editions. Be sure and get up the urine and urinary microscopic, and pathological and histological work thoroughly, also the uses and names of all surgical instruments and appliances, and if at all shaky in clinical work do not venture to present yourself before doing a certain amount of ward-work. And last, but not least, do not think that because you *are* forty years of age and practise in London *anything* will do for Durham, or you will regret it.

I am, Sirs, yours faithfully,

Oct. 3rd, 1898. M.D.

SAVE US FROM OUR (CLERICAL) FRIENDS.

MR. CLAGUE, of Castletown, Isle of Man, is to be sincerely sympathised with on account of the, doubtless kindly meant, advertisement given to him by Canon Christopher, of Oxford, in the *Record*. The worthy canon's article is headed "Sleeplessness: A Prescription." He explains that after a number of eminent London medical men had failed to relieve him "Dr. Clague, of Castletown, Isle of Man, took me in hand. He prescribed for me a sedative mixture which not only, under God's blessing, cured me, but also keeps me cured. I have never had a really sleepless night for eleven years. ..... Dr. Clague's 'Sedative Mixture' never interferes with any regular habit and I have never had a headache or any other ache for eleven years. I do not know what ingredients are combined in the mixture, but if any one of your readers wishes to know, let him send a P.O. for 2s. to Mr. R. K. Kermode, chemist, Malew-street, Castletown, Isle of Man, and ask him to send a small bottle of the 'Sedative Mixture' which he has sent me for about eleven years and the prescription. No one must expect an answer if he merely writes for the prescription. . . . If any sleepless sufferer can afford to take a bed for a week at Fort Island Hotel, near Castletown, Isle of Man, he will enjoy the sea air, and can consult Dr. Clague, whose fees are very moderate. . . . Dr. Clague's ability is well known to his medical brethren in Douglas, who occasionally call him in for consultation in specially difficult cases." Really, as Canon Christopher says he is seventy-eight years of age, it might have been supposed that he was old enough to know better than to write such a letter. A postal order sent as directed brought an 8 oz. mixture labelled "The Sedative Mixture as recommended by Canon Christopher. . . . N.B.—The Prescription is not supplied."

"THE MEDICAL DIRECTORY."

To the Editors of THE LANCET.

SIRS,—The Medical Directory is such a useful and generally admirable publication that any question which tends to eliminate blemishes will, I am sure, be welcomed by the editors. The list of hospitals and schools of medicine in London is apparently arranged alphabetically, only on a very mixed system. It commences thus: Bartholomew's Hospital (St.), then follow Charing-cross, Guy's, King's, London, Middlesex, and then come St. George's, St. Mary's, and St. Thomas's. Now, if all the hospitals called after a saint are to be inserted alphabetically under S, why should the Apostle Bartholomew be ignored? If the alphabetical arrangement is to be taken from the names of the saints, then St. George's should precede Guy's and St. Mary's precede Middlesex. The present arrangement is a hopeless mixture.

I am, Sirs, yours faithfully,

Oct. 10th, 1898. C. P. H.

To the Editors of THE LANCET.

SIRS,—There is something to be said for and against the present arrangement of the Medical Directory, but it would be quite easy with the addition of a few extra pages to increase its usefulness. All that is required is an alphabetical list of names at the beginning of the book and an indication of the section where the full names and qualifications, &c., can be found.

I am, Sirs, yours faithfully,

Oct. 3rd, 1898. OPS.

POWDER PUFFING.

WE have received the wrapper of a packet of baking powder upon which is printed a testimonial signed "W. Tibbles, M.R.C.S., L.R.C.P., L.S.A." Mr. Tibbles would do well if he took steps to have his name removed from such undesirable publicity.

ADVERTISING.

A CORRESPONDENT has forwarded to us a card, of which we reproduce a portion:—

Notice of Removal.

Dr. Burslem Rotheroe

has removed from

.....

to

.....

1st Sept., 1898. .....

The card was forwarded in an envelope addressed to (we omit the name) "Col. ——, Esqre." It is not usual to put "Esq." after a name bearing a preceding title. Moreover, the envelope was unstamped and surcharged. Our correspondent informs us that he has never been a patient of the medical man in question. Mr. Rotheroe must know that it is not professional for any medical man to send "change of address" cards to others than his own patients.

Mr. R. Eustace will find the names of the examiners in the current Calendar of the College under the heading of Officers, &c. It is very unlikely that the qualified man stands any better chance than the unqualified, or that the man who has been rejected stands any better chance than the virgin candidate.

A Registered Medical Student has omitted to enclose his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Kingston News, Bradford Observer, Birmingham Gazette, Scotsman, West Middlesex Advertiser, Manchester Guardian, Western Morning News, East Anglian Times, Nottingham Guardian, Woolwich Herald, Warwick Times, Leicester Post, Westminster Gazette, Times of India, Pioneer Mail, Walsall Advertiser, Glasgow Herald, Sheffield Telegraph, Watford Observer, Galloway Advertiser, Sussex Daily News, Dundee Advertiser, Brighton Gazette, Builder, Liverpool Daily Post, Citizen, Architect, Leeds Mercury, Lincoln Chronicle, City Press, Yorkshire Post, Grimsby Daily Telegraph, Bristol Mercury, Radnorshire Standard, Household Words, Western Mail, Sanitary Record, Local Government Chronicle, Mining Journal, Hertfordshire Mercury, Reading Mercury, Daylight, Chelsea Mail, Local Government Journal, Surrey Advertiser, Eastern Daily Press, Weekly Free Press and Aberdeen Herald, The Evening Reporter, Pontypridd Chronicle, Arbroath Herald, Redworth Observer, Dereham and Watton Standard, Isle of Man Examiner, Whitehaven Advertiser, Bristol Times and Mirror, Barry Herald, Chard News, Fish Trade Gazette, Paddington Gazette, Daily Chronicle, &c.,*

The Harveian Oration

ON

THE INFLUENCE OF CHARACTER AND RIGHT JUDGMENT IN MEDICINE.

Delivered before the Royal College of Physicians of London on Oct. 18th, 1898,

BY SIR DYCE DUCKWORTH, M.D., LL.D. EDIN.,

FELLOW AND TREASURER OF THE COLLEGE; HONORARY FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND; PHYSICIAN AND LECTURER ON MEDICINE AT ST. BARTHOLOMEW'S HOSPITAL; HONORARY PHYSICIAN TO H.R.H. THE PRINCE OF WALES.

SIR SAMUEL WILKS (President of this College), FELLOWS, AND GENTLEMEN,—The honourable task which is imposed upon me to-day carries with it, year by year, a heavier burden and an increased responsibility. I suppose that not fewer than 180 Harveian Orators have taken their places in this venerable College to carry out the project of that great man whose character and work we so appropriately commemorate on this festival of "the beloved physician." When we reflect that the orators have in nearly every instance come fresh to the task, have brought all their learning and literary skill to bear upon it, have not seldom in the past clothed it in the purest Latin or the most classical English, and have no less enriched both the science and art of medicine by many of these efforts, the latest of that band may well invoke to-day some of the divine *ἐνθουσιασμός* to descend upon him as he sets out to follow the well-worn road which lies before him. For myself I may say that I yield to none in the interest which this duty has for me. As Physician to the great hospital which Harvey served,[1] as his successor in this College, *longo intervallo*, in the capacities of its Treasurer[2] and Lumleian Lecturer,[3] and as one of the eight Fellows, of whom only three now survive, who on this day fifteen years ago had the privilege of bearing his body, "lapt in lead," to its final resting-place on the occasion of the translation of his remains at Hemel Hempstead, I find myself in particular sympathy with the object and circumstance of our meeting to-day.

Inasmuch as Harvey himself conceived the idea of this Oration[4] and definitely laid down the specific objects of it, I take it to be the plain duty of the orator to obey his directions as loyally as possible, and in doing so I hope to find suggestive lines of thought for interesting and fruitful comment. It is therefore my duty first to commemorate some of the greatest benefactors of this College; secondly, to incite our Fellows and Members to search out and study the secrets of nature; and thirdly, to urge a spirit of gracious courtesy and kindliness amongst ourselves. Harvey's primary consideration in this matter was without doubt to maintain the position and dignity of his beloved College, to foster its usefulness, and to keep it well abreast of the knowledge and learning of the day, so that by its influence it might impart a high and beneficial tone to the whole commonwealth of medicine in England. It was a high ideal, but not too high for the best spirits in this College; and that, sir, and no less, I will venture to say, is our ideal of its position to-day—a day in which we bear witness to many and radical changes of circumstance indeed, but in which, notwithstanding, we are still full of energy and good purpose, full of strong will and intention to hold that position and, if possible, to add to it.

When Harvey enjoined upon the orator the duty of commemorating the chief benefactors of the College the task was comparatively simple, but happily for us, thanks to the many benefits our Fellows have conferred upon our commonalty, it would now be little less than wearisome to enumerate them and allude even briefly to their varied benefactions. Few will demur to the statement that Harvey himself has been our greatest benefactor, whether by reason of the immortal lustre he shed upon us by his epoch-making discovery and teaching, or in respect of his substantial gifts and the bequest to us of his patrimonial estate. And no less, I would add, has been the boon he conferred upon this College for all time by the legacy of his personal character and qualities—qualities which none of his successors here can afford to forget or neglect. Some of our greatest benefactors have not been, so far as I can learn, recently commemorated by our orators. I will, therefore, claim your indulgence while I praise some of the good men to whom we are indebted for many of our privileges and opportunities of usefulness.

Foremost I place Thomas Linacre, our founder and first President in 1518. Let it be remembered that he designed this Corporation as well for the benefit of the public as of the profession. His wisdom, scholarship, and moral excellence rendered him, as has been said, "the ornament of his age." The College meetings were held in his private house,[5] which he made over to the Physicians, and this was our first building, subsequently enlarged and used till 1614. The Lumleian Lectures were first delivered there. As our learned orator two years ago showed, Linacre may be regarded as "the intellectual grandfather of Harvey," and in virtue of his translations of Aristotle and Galen, Dr. Payne placed him in the front rank of the medical Humanists, pointing out, further, as we well remember, how out of these scholarly efforts grew the scientific movement which led to a truly fertile study of biology.

John Caius, nine times elected President, must ever be revered here for his beneficent efforts. He erected a monument in St. Paul's Cathedral to Linacre, whom he is held to have taken as his model in life. Caius began our volumes of Annals and thus set an example to all succeeding registrars which has certainly been well followed to the present time. He instituted those "ensigns of honour" by which our President is distinguished amongst us. He was the first to introduce and teach practical anatomy in England. His scholarship and literary works, his method and precision, rendered him one of the most noteworthy men our profession has ever had in any country. We recall his efforts and munificence in refounding Gonville Hall at Cambridge, a college which has sent to us here, and still continues to send, some of our most distinguished Fellows and Members. Harvey's lines of thought and study were probably, as Dr. Payne suggests, much projected under the posthumous influence of the second founder of his college.

I merely mention the names of Caldwell and Lord Lumley, the founders in 1581 of our Lumleian Lectures which Harvey held for forty-one years and in which he expounded his original investigations on the circulation of the blood, and refer next to William Gilbert, sometime Treasurer, and President in 1600. Gilbert was the father of experimental philosophy in England. His famous work "De Magnete" first directed the mind of Galileo towards this and kindred subjects. He bequeathed to the College his library, globes, and instruments, most of which perished in the great fire of 1666, only 140 volumes of his books being rescued.

We commemorate Theodore Goulston as the founder, in 1632, of the lectures bearing his name, which he designed to be delivered in each year by one of the four youngest doctors of the College. He was excellent both as a physician and a scholar and published translations from Aristotle and Galen.

Baldwin Hamey, junior, ranks with Harvey amongst our greatest benefactors. He redeemed at his own cost the first College building in Amen Corner from a possible confiscation to the spoliators of Church property in 1651, contributed largely to the fund for rebuilding the College after the great fire, and wainscoted the coenaculum with Spanish oak, some of which now lines the walls of our Censors' room. In 1672 he made over for ever his Essex property of Ashlyns, an estate of 400 acres, for its immediate benefit, including, by the way, an equivalent sum to that appointed by Harvey as the honorarium of the Harveian Orator. Hamey's bust executed in 1684 and his portrait both look down upon us to-day from these walls. The agricultural depression of recent years has unfortunately affected the property so nobly bequeathed to us, but we still count it amongst our best certain sources of income.

We honour the memory of Francis Glisson, sometime President.[6] Working on the lines of research laid down by Harvey, Glisson enlarged the knowledge of anatomy and pathology, and of the fruits of his studies we avail ourselves in daily practice. In thus wresting veritable secrets from

nature[7] he was truly a benefactor to this College, and in respect of his work on the subject of rickets, still known as the English disease, a benefactor to his countrymen.

We may not omit to recall to memory the benefactions of the Marquis of Dorchester. A diligent and widely read student in the learning of his day he was urged by Harvey and others to join this College in 1656. Two years later he was admitted to the Fellowship. Sympathising with the College in the loss of its library, and to show his respect for the profession, he bequeathed a collection of books of the value of £4000 and contributed £100 towards the library. What a splendid example was this, and how little has it been followed in the last two centuries.

It is a fact to note here and now, for while we have had in recent times some noble instances of beneficence for the institution of lectureships and prizes we have had hardly any gifts or bequests in the form of endowments for the College itself—endowments which I, as your treasurer, can well certify are more than is commonly believed necessary to enable us to maintain our position, our fabric, and our library. Those of us who are engaged in teaching in this metropolis have to acknowledge that in these days the vital interests of higher learning make little appeal to the sentiments or generosity either of wealthy peers or commoners whose interests lie largely in London; while we take note of the fact that learned institutions in the provincial cities, void as yet of traditions, have no difficulty in arousing and stimulating such qualities in the hearts of their citizens and enlisting from them noble gifts and benefactions. This is a Royal, but unendowed, College, yet it is constantly appealed to for advice by the several offices of the State which thus receive gratuitous assistance for the benefit of the public. I venture to think that a corporation such as this well commends itself to the consideration and substantial liberality of persons of wealth and patriotic intelligence resident in London. We might at least look for one such donor as Lord Dorchester in each century, and the College will welcome such benefactors and not fail to commemorate their good deeds in the days to come, thus securing for them an enviable immortality.

Let us praise William Croone, Fellow of Emmanuel College, Cambridge, a Censor of this College in 1679 and founder of the lectureship which bears his name. With his memory we associate that of his widow, Lady Sadlier, who loyally carried out his wishes in providing a fund for the endowment of the lectures.

I turn now to hold up in honour some others of our distinguished Fellows who by their attainments and splendid personal characters have conferred undying benefits upon our College and through it upon the profession of physic. We are perhaps too much disposed to commemorate the scientific achievements of our great men, but let us not be unmindful of their characters. We know that genius is not always coincident with the highest moral or spiritual perfection, but when both these qualities are graciously combined in anyone we feel that we are in the presence of a truly great man, of one who becomes a personage and a power for good in his day and generation. In such a profession as ours we can never afford to lose sight of the preponderating influence of character in all who join our ranks and have to minister to every grade of our common humanity. The training which enabled Harvey to be the man we know him to have been, the scholarly, wise, even-minded, and unworldly man, was that which best begets men of his mould. No mere technical or narrow training could by itself have produced him. His mind was expanded by wide reading, by travel, by knowledge of men and manners, by contact with the best spirits of his age, and by honest service to both rich and poor. His character, too, was formed by deep religious sentiment, by a pure faith, and by gentle sympathy with his fellow-men. He probably owed much, as many great men do, to the influence of his mother, for we know that she "was reverensed of her children."

In Harvey we have indeed a splendid model of the ideal physician, for not only have we to cultivate wide learning for its own sake, and its unquestionable influence upon us, but we have to see to it, if anything more assiduously, that we be men of the highest character. If the factor of high character was a great one in Harvey, and a gracious achievement in the seventeenth century, can it be doubted that it is a less imperative quality for us in the declining years of the nineteenth? I almost fear that in this restless age, so prolific in novel developments, there have opened out before us, more than is easy to steer clear of, many new channels wherein our moral integrity may be severely tried; and we may not seldom be tempted by a thoughtless and credulous public to deviate into courses which a strictly disciplined and finely tempered nature must ever recoil from. Yes, character must always be the mainstay and regulator of our conduct both amongst ourselves and towards the public whose servants we are. This requirement should receive emphatic recognition in every commemoration of Harvey. We may well learn from the examples of Harvey and from others which I shall venture to present to you what manner of men physicians should strive to be. If time permitted me I might say much in praise of Arbuthnot and Mead, of Hale, who left us £500 for our library, and of Freind; but I pause to commemorate William Heberden, author of the famous "Commentaries,"[8] who, by his learning, wisdom, and high character, left us a legacy of which the College may be proud. We may understand what manner of man he was if we realise what Dr. Macmichael wrote of him: "From his early youth he had entertained a deep sense of religion, a consummate love of virtue, an ardent thirst for knowledge, and an earnest desire to promote the happiness and welfare of all mankind. By these qualities, accompanied with great sweetness of manners, he acquired the love and esteem of all good men in a degree which perhaps very few have experienced."

Sir George Baker, President for ten years, was pre-eminent as a scholar and practical physician. His method of research on the nature of Devonshire colic has truly been pronounced to be a model for the conduct of scientific medical work. Greatly appreciated and honoured in his time, his memory remains with us a precious heirloom.

I speak next of Matthew Baillie, who delivered the Harveian Oration exactly a century ago, but, so far as is known, did not publish it. Baillie was at that time thirty-seven years of age and engaged in teaching anatomy. We may perhaps assume that some anatomical exposition formed the subject of his oration, for though he had then been in practice for twelve years he did not begin to record his clinical experiences for twenty-one years afterwards, hoping to secure the leisure, which he never did, to elaborate this work. We may greatly regret this inability, for his clinical records were admirable and in advance of their time. Baillie's energies were therefore devoted to his patients when his powers and intellect were at their best, and, as is not seldom the case when physicians of eminence are eagerly sought by numerous patients, but little time and strength were left to pursue fresh study or publish newly acquired experience. Of such men little remains to tell of their special skill or of the qualities they exhibited in practice. Baillie worked seventeen hours a day. His benefactions to this College were great. He gave in his lifetime his private collection of morbid specimens, now in our Museum. He bequeathed at his death, in 1823, a legacy of £300, with all his medical books and the copper-plates of his work on "Morbid Anatomy." This book was the product of his industry in his uncle William Hunter's museum and is of especial value because in his later editions of it he described the clinical features of the cases which furnished the morbid specimens. He was thus one of the pioneers of the modern school of physicians, trained on the lines laid down by Harvey to prosecute research by observation and experiment. I conceive that Baillie may be regarded as the English Morgagni of his time, but he was even more lucid and precise than his great predecessor.[9] He left on record a very pregnant sentence which we shall do well to remember, for we need its wisdom now as much as in the days when it was written.[10] "I am persuaded," he remarks, "that the most successful treatment of patients will

[7] "I am glad to be able to-day for the second time to credit the English nation with the service of having made the first attempts to define the character of life. It was Francis Glisson, who following expressly in the footsteps of Paracelsus, investigated the *principium vitæ*. If he could not elucidate the nature of life he at least recognised its main characteristic. This is what he was the first to describe as 'irritability,' the property on which the energy of living matter depends."—Professor Virchow, Huxley Lecture, delivered in London, 1898.

[8] Commentarii de Morborum Historia et Curatione"—a posthumous work, 1802.

[9] Morgagni was born twenty-five years after Harvey's death. Baillie was born seventy-nine years after Morgagni.

[10] "Lectures and Observations drawn from my own experience upon a considerable number of diseases." London. 1825. (A posthumous work, of which only 150 copies were printed for private circulation in accordance with the directions in Dr. Baillie's will.)

depend upon the exertion of sagacity,[11] or good common sense,[12] guided by a competent professional knowledge; and not by following strictly the rules of practice laid down in books even by men of the greatest talents and experience." Baillie acknowledged that he owed a good deal to Dr. David Pitcairn of St. Bartholomew's Hospital, who was his firm friend. He learned from him that rheumatism was frequently the cause of disease of the heart—a fact which had not been previously recognised; also, that ague was often not amenable to the influence of bark unless a course of calomel preceded it. An example of Baillie's sagacity is furnished by his conjecture that hydatids were animals, an opinion not held at that time. To tell only of Baillie's scientific work, however, is to disclose but a part of his illustrious career. As Sir Henry Halford said of him in announcing his bequests to the College, "Justice cannot be done to his medical character unless that important feature in it which appeared in every part of his conduct and demeanour—his religious principle—be distinctly stated and recognised." As in Harvey, so in Baillie: "Ample converse with one of the most wonderful works of the Creator—the formation of man—inspired in him an admiration of the Supreme Being which nothing could exceed." He had indeed "looked through nature up to nature's God." His moral loftiness and his splendid character secured for him the deepest regard and affection of his professional brethren. We cannot neglect to commemorate and praise the man of whom so much could be said by a contemporary who knew him well. May Baillie's spirit and influence ever prevail in this College!

It would be a pleasant task to illustrate further the value and charm of high character when blended with learning and skill in our profession by the splendid examples of Henry Halford, Peter Mere Latham, Thomas Watson, and George Burrows, who have lived and laboured in our own day, shed lustre on this College, and earned places amongst our worthiest benefactors. But I must desist. By Harvey's direction I exhort you, and I exhort myself, to imitate such men as we have praised and commemorated; and in striving to this end we shall find help and inspiration if we look back and discover what manner of men the English physician was in the earlier part of this century. He was then regarded as combining in his person, "not only the qualifications necessary for the successful practice of physic, but those which give dignity to his professional and respectability to his private character. He was distinguished by large attainments as a scholar, by sound religious principles as a Christian, by practical worth and virtue as a good member of society, and by polished manners as a well-bred gentleman."[13] I trust that I may be pardoned for dwelling at some length on this part of Harvey's charge, since, to the best of my belief, it has not received prominent notice from my predecessors during the last thirty years.

I have next to repeat to you to-day our great master's injunction "to search and study out the secrets of Nature by way of experiment." It may truly be said that there is no lack of research in our time into the secrets of nature. On the contrary, we are presented with a plethora of products emanating from our laboratories as the result of the original inquiries; and our difficulty now is to discover their true value and to find a fitting employment for the knowledge thus brought to light. The younger men amongst us are naturally attracted both to fresh research and the application of its fruits in clinical work. The elders, by their longer experience of humanity, both in its well-being and its woes, are less eager to engage in experimental methods and prefer to practise the hard-earned principles which have gradually commended themselves to them.[14] Do what we will, however, truths either new or in fresh aspects move steadily onwards and come in the fulness of time to occupy the field. For our purposes as physicians, the secrets of nature disclosed in the laboratory require to be brought to the touchstone of clinical experiment and observation. If they be veritable facts they serve at once to advance our art by enlarging our powers to cope with diseased conditions; while if the results of laboratory experiments have been incompletely wrested from Nature they will fail to aid us, though, perchance, they may prove suggestive. Of some, I think, it may be said that they fail *primo visu* to commend themselves to our common sense. I will support this assertion by a reference to some recent laboratory researches undertaken in America. With a view to determine the influence of alcohol in morbid conditions certain rabbits were inoculated with streptococci and other microbes and then kept daily in a state of acute intoxication by alcohol. These animals showed the effects of the inoculation earlier and more severely than rabbits which were similarly infected, but not alcoholised. It has been proved that alcohol in poisonous doses exerts a negative chemiotaxis in the tissues and it is also well known that a prolonged abuse of it by man causes widespread degenerations.

On the strength of these and similar phenomena we are gravely warned from the laboratory that it must be disastrous to employ even moderate doses of alcohol in inflammatory conditions of disease in the human subject. I trust that we may keep our minds clear on this matter and pray daily for a right judgment in all things. The laboratory operator may tell us that alcoholic stimulants are bad for this or that disease, but we shall maintain that they are sometimes very good for the patient. The practitioner who could allow the teaching of such experiments as I have quoted to influence his bedside treatment of patients suffering from acute diseases would, in my opinion, possess neither clinical instinct nor knowledge.

Yes, clinical instinct or intuition, for I maintain that none can be skilful in medicine without it. Call it sagacity, common sense, or what you will, the physician must possess it, and it must direct his methods, whether they proceed from the laboratory or elsewhere. The present danger in this matter—and it is a real one—is that the modern spirit of research tends in some degree to withdraw our attention from facts and principles which have been well established for us by the clinical acumen of past masters of our art, and which in the best interests of our patients we can ill afford to lose. New methods thus come to displace old ones and not always with benefit. While keeping open minds we must not dispense with the caution that the new is not necessarily the true. I have ventured to utter this note of warning, but I would not for one moment be regarded as indifferent to the unquestioned triumphs of modern laboratory research in all directions. While Harvey clearly intended the orator of each year to be in the first part of his discourse *laudator temporis acti*, he was the last man to plant himself down immoveably, and rest content as though the goal of research had been reached. Knowing too well in his own day the evil and tyranny of stereotyped traditions and beliefs,[15] and shrewdly foreseeing the necessity of perpetual progress in medicine, he definitely charged us to encourage fresh research; and therefore I will express my entire agreement with the words used by one of my esteemed predecessors and former colleagues eight years ago in his oration: "It will be an evil day for medicine and physiology if ever the results of laboratory work are held to have no bearing upon

[11] ἀγχίνοια (Aristotle).

[12] "Common Sense (a faculty of more use to the practical physician than all the science of a Newton), and approved by the experience of every age." "A proper decision as to treatment requires experience, tact, and long-headedness."—John Goodsir, "Anatomical Memoirs." W. Turner, M.B., with biography by H. Lonsdale, M.D., p. 77. Edinburgh: 1868.

[13] Obituary notice of George Williams, M.D., Vice-President of Corpus Christi College, Oxford, and Professor of Botany; Fellow of this College.—Gentleman's Magazine, March, 1834.

[14] "No man who had attained the age of forty years was found to adopt Harvey's doctrine of the circulation; it had to win its way under the safeguard ..... of the youthful and unprejudiced spirits of the age."—Life of Harvey, p. xlvii., R. Willis.

[15] "The facts cognisable by the senses wait upon no opinions. The works of Nature bow to no antiquity; for, indeed, there is nothing either more ancient or of higher authority than Nature." "We are to strive after personal experience, not to rely on the experience of others. ..... Nature is herself to be addressed, the paths she shows are to be boldly trodden, for thus, and whilst we consult our proper senses, from inferior advancing to superior levels shall we penetrate at length into the heart of her mystery." "True philosophers, who are only eager for truth and knowledge, never regard themselves as already so thoroughly informed but that they welcome further information from whomsoever and whencesoever it may come; nor are they so narrow-minded as to imagine any of the arts and sciences transmitted to us by the ancients in such a state of forwardness and completeness that nothing is left for the ingenuity and industry of others." (Letter to Dr. Argent and the Fellows of the College). "Nature—the word that stands for the baffling mysteries of the universe. Steadily, unflinchingly, we strive to pierce the inmost heart of Nature, from what she is to reconstruct what she has been and to prophesy what she yet shall be. Veil after veil we have lifted and her face grows more beautiful, august, and wonderful with every barrier that is withdrawn."—Presidential Address at the British Association Meeting, Bristol, 1898: Sir William Crookes. "Nature is the art of God."—Sir Thomas Browne. 1635.

medical practice."[16] So long as we prudently avail ourselves of these results we shall not fail to add to the credit and beneficence of our art. The so-called "practical" man is the one likely to avail himself of immature laboratory researches. As Professor Kanthack remarks: "Paracelsus is not yet dead. He snatches incomplete researches out of the laboratories and applies them in the treatment of diseases, the pathology of which he does not understand, and his influence makes itself felt in laboratories to the discredit of medicine."[17] What we greatly need now in England are research laboratories attached to our hospital wards and post-mortem theatres, and no less a select staff of fully-trained investigators available for service throughout the empire. It is surely humiliating that we permit researches to be made for our benefit in various parts of our dominions by foreigners, while many of our countrymen and countrywomen, owing to ignorance and mawkish sentimentality, are doing their best to debar the training of such men in England.

The day in which it has been affirmed that there is a gulf fixed between physical and spiritual science is, I think and hope, fast drawing to its close. The temper of mind which leads, however honestly, to such a belief was not that of Harvey nor, indeed, has it been that of the majority of physicians of this College whom we reckon among the most exemplary men of the past. I will venture to say, further, that it is not the aspect in which such matters are viewed here and now. As Willis observes, Harvey "seized every opportunity of giving utterance to his sense of the immediate agency of the Divine in Nature."[18] He had no fear either of the processes or the results of research. We can imagine his approval of the following sentences in the "Religio Medici" which he must have read: "There is no danger to profound these mysteries, no *sanctum sanctorum* in philosophy. The world was made to be inhabited by beasts, but studied and contemplated by man; 'tis the debt of our reason we owe unto God, and the homage we pay for not being beasts. ..... Those highly magnify Him, whose judicious inquiry into His acts, and deliberate research into His creatures, return the duty of a devout and learned admiration. Therefore:

> "'Search where thou wilt; and let thy reason go,
> To ransom truth, e'en to the abyss below;
> Rally the scattered causes; and that line
> Which Nature twists be able to untwine.
> It is thy Maker's will; for unto none
> But unto reason can He e'er be known.'"

I will now refer to some researches which are of especial interest to us at the present time. They relate to bacteriology. Starting with the conception of bacillary invasion of the body,[19] and the mischief thereby engendered, we naturally seek to destroy the germs themselves and to undo their evil effects. Preventive medicine has for its aim the provision for us of an environment destitute of noxious germs and is now achieving brilliant success in its progress; but in practical medicine the physician has as yet to be satisfied with the endeavour to combat the ill effects of such germs as have gained entry to the body by restoring to the natural standard that impaired vitality of the system which has enabled the bacteria to gain the upper hand. In the gravest cases, where bacillary invasion is widespread and rampant, as in the exanthemata, continued fevers, or pyæmia, we are in the presence of a dosage of toxins so overwhelming that it cannot be met by any adequate systemic resistance. We have as yet but few antitoxins available in practice, though we look with confidence in the future to the fruitful labours of our laboratories for more of such agents.

Our present inability, then, leads us to consider the solitary factor on which we have to depend and which is in each case to determine the issue. We term it the bodily, or tissue, resistance. What is the full significance of it? The varying vulnerability of the individual is the factor before us in each patient and we have to gauge this as nicely as we can. A toxic dosage which is certainly lethal for some is not so for others. The soil, so to say, is, or has somehow become, favourable for the full development of the toxin in the one case, while in the other a degree of immunity exists which proves adequate to overcome the noxious dose, the soil being unfavourable for its full development. This is a matter of the constitution, a personal peculiarity or proclivity, either inherited or acquired. We call it the personal factor in each case and therefore a physician never speaks of treating *diseases* but of treating *patients*.[20] Our knowledge of these personal factors is not large and as yet not very accurate. Theoretically, we might conceive that the highest condition of health, with full integrity of the vital organs, should provide the fullest measure of immunity against all forms of bacillary toxin, whereas in practice we know that in the case of many of them, as in that of small-pox, cholera, or diphtheria, such immunity is of little or no avail and that death may result from an overpowering multiplication of the specific peccant matter. Happily, we can now control the invasion of small-pox and are able materially to counteract the diphtheritic virus by an antitoxin. And so with some other diseases.

Let us take the case of persons of that habit of body in which tuberculosis is apt to occur. We must regard them as presenting in some of their textures an appropriate *nidus* for the cultivation of the specific bacilli. Could we shield them from all possible contact with these germs we might fairly anticipate for them an average longevity, though, as I shall presently show, their textures constitute a bad soil for the inroad of most diseases. We know that under certain depressing conditions, whether of climatic or other environment, the tissues even of fairly healthy bodies lose their resistance and become a prey to the activity of various bacillary parasites, affording examples of sundry specific disorders. The problem before us in all such cases is to determine, if we can, the ratio of the force of resistance to that of the infection. Too often we have but to study the course of the disease in order to decide this point, and while treating the patient, as we watch the contest,[21] we sometimes discover evidence of inhibiting factors which prove adequate to check the mischief arising from parasitic invasion. We have an example of this in the case of a proclivity to gout, which tends markedly to check tuberculous invasion, and when this occurs to protract its course.[22] There is reason to believe that some constitutions are practically invulnerable against the infections of tuberculosis, rheumatism, marsh-poison, and others. We need to study carefully the causes of such immunity since, as Harvey urged, many problems are to be solved by the investigations of exceptional cases.[23]

The subject of scrofula is just now engaging the attention

---

[17] "The Science and Art of Medicine." Address to the Abernethian Society of St. Bartholomew's Hospital. St. Bartholomew's Hospital Journal, August, 1898.

[18] "Nempe agnoscimus Deum, Creatorem summum atque omnipotentem, in cunctorum animalium fabrica ubique presentem esse, et in operibus suis quasi digito monstrari."—"De Gen. Animalium," Exerc. liv. "Harvey's education and his epoch made him, as a believer reverential: he was by nature modest, and being a sound observer he was neither superstitious nor illogical. ..... Far above all he was taught by Nature."—Harveian Oration, 1865, Sir Henry Acland. "Physical and spiritual science seem to the world to be distinct. One sight of God as we shall one day see Him will show us that they are indissolubly and eternally the same."—Charles Kingsley. "Science is great, but she is not the greatest. She is an instrument and not a power—beneficent or deadly, according as she is wielded by the hand of virtue or vice. But her lawful mistress, the only one which can use her aright, the only one under whom she can grow and prosper and prove her Divine descent, is Virtue, the likeness of Almighty God."—"Roman and Teuton," Charles Kingsley, 1860.

[19] Athanasius Kircher, a Jesuit, wrote in 1659, two years after Harvey's death, that "the propagators of the plague are little worms, so small, fine, and delicate that they cannot be recognised by the senses." It was left for a Japanese bacteriologist, Kitasato, to discover in 1894 the bacillus specific to plague.

[20] This is no new idea, although it is necessary even now to emphasise it. It was clearly in the mind of Aristotle, as may be gathered from the following passage: Φαίνεται μὲν γὰρ οὐδὲ τὴν ὑγίειαν οὕτως ἐπισκοπεῖν ὁ ἰατρός, ἀλλὰ τὴν ἀνθρώπου, μᾶλλον δ'ἴσως τὴν τοῦδε· καθ' ἕκαστον γὰρ ἰατρεύει'—Nicomachean Ethics, I. 6, xvi.

[21] A passage in Harvey's Anatomical Exercise (lvii.) on the Generation of Animals affords a remarkable prevision on his part respecting the reaction of the bodily tissues to the intrusion of irritants. Referring to the effect of spider poison when introduced by a prick under the skin he wrote: "Erat tamen in cute quod discerneret, quippe eodem loco, ubi venenata punctio contigerat, subito sese in tuberculum contraxit, induitque mox ruborem, calorem, atque inflammationem, tanquam ad *pugnam* et nocentis mali expugnationem se roboraret et accingeret." What have we here but a forecast of the modern researches of Metchnikoff and others upon the action of phagocytes in inflammatory foci? The idea of a contest in the involved textures was, I think, singularly prophetic of the histological discoveries to be made some 230 years later and displays the intuition of Harvey in his study and interpretation of the secrets of Nature without any other aid than his simple vision.

[22] That this is not due to the fact that tuberculosis is a disease mainly of youth, while gout occurs chiefly in middle or later life, as has been alleged, is, I think, proved by the practical immunity of the children of gouty inheritance from strumous manifestations and tuberculosis. Senile struma is certainly recognised and blended conditions of gout and struma may be met with in advanced life.

[23] He wrote to Vlackveld of Harlem within a few weeks of his death: "There is no better way to advance the proper practice of medicine than to give our minds to the discovery of the usual law of nature by the careful investigation of rarer forms of disease."

Digitized by Google

of some pathologists and I propose to consider briefly some facts in relation to this condition. Koch's great discovery is supposed by many to have explained its pathogeny and to have laid to rest the old disputes respecting the connexion of struma and tuberculosis. In my opinion this matter is by no means disposed of solely on a bacteriological basis. The presence of a few tubercle bacilli in the lympharia may be a factor in a given case, but their presence does not explain all that we recognise as constituting the obvious condition of struma. Our predecessors took a wider view of the matter and we must still hold by some of their conceptions. The old belief was that scrofula—that is, an obvious manifestation of tuberculous disease—was a condition capable of transmission from parent to child. The indications of this state were then rightly determined, though now we interpret them differently, and were recognised by the ill-developed alar thorax, long, clumsy limbs, downy forehead and back, precocious intellect, and various other characteristics. But in 1846 Dr. Robert M. Glover pointed out that a careful distinction should be made between the predisposing constitution and the actual processes of strumous disease, between the *ens in potentia* and the *ens in actu*, and that thus such subjects widely diverged from health before tuberculous deposits took place.[24] This brings us to our view of the matter to-day, since we now believe that the heredity of scrofula means no more, but no less, than an inherited feebleness of bodily textures in which tuberculous bacilli are apt to thrive if they gain entrance at any point, a vulnerability of tissues affording little or no resistance to such an invasion. This diathetic condition or tissue-proclivity is what is transmitted, and it may be the outcome of long antecedent inheritance from an ancestry in which tuberculosis has from time to time manifested itself. We know that direct transmission of bacillary tuberculosis is possible, but that it is of the extremest rarity; also, that direct transmission of tubercle from patient to patient is possible, but very difficult of absolute proof. There is reason, too, for the belief that infection may occasionally spread from the impregnated air of certain dwelling-houses, leading to repeated cases amongst the occupants, provided they present the necessary degree of susceptibility.[25]

Our present point of view could never have been reached till we were made familiar with the infecting parasite which, as we believe, alone brings us in face of the *ens in actu*. Eighty-eight years ago Matthew Baillie, by naked-eye observation alone, fully recognised the fact that the caseous matter in the lympharia and in the lungs was identical and now we have the explanation of it. It has been suggested that the condition of struma is dependent on a latent state of tuberculosis. This idea must be discarded if we regard all tuberculous activity as due to bacillary influence. Yet another theory, recently advanced, deserves consideration, as it opens up a large question in bacteriology. It is urged that the condition of struma may be due to the presence in the body of tubercle bacilli in some early or pre-existing stage of development, which lead to other manifestations than those recognisable as tuberculosis. It is true that we have as yet but little knowledge respecting the exact biological position of the bacillus as commonly met with. In this condition it may possibly, as Woodhead and others suggest, merely represent one phase in the life-history of a higher fungus, allied to the actinomyces, which in certain stages of its existence leads a saprophytic life, its parasitic and pathogenetic phases being merely temporary. Without following up this suggestive hypothesis some support is added to the idea of latency, or of an unrecognised, spore-like (resting stage) condition of the tubercle bacillus by the fact that cases of tuberculous outbreak sometimes supervene when caseous structures or their vicinity suffer from injury and a consequent lowered vitality. This occurrence points to the general dissemination of microbes from some distant focus of long-past or forgotten disease, a development and migration, dependent, possibly, on some law of which we are at present ignorant. We have instances illustrating it in tuberculous meningitis following injuries to the head, in acute pulmonary tuberculosis following injuries to the testis, or to joints, once the site of tuberculosis, or supervening on operations for tuberculous anal fistula, while in cases of Addison's disease (adrenal tuberculosis) injuries to the spinal column are sometimes suspected as the primary exciting cause.[26]

In many of the enlarged lympharia of strumous persons neither tubercle bacilli nor caseous matter can be detected. This fact suggests that the tendency to react vigorously to irritants other than tuberculous is a specific factor and quality of the lymphatic system in strumous individuals. These swollen lympharia doubtless present a good soil wherein tubercle bacilli may lodge and induce caseation should they gain entry. This peculiarity of the lymphatic system in the strumous subject justifies us, in my opinion, in retaining in the old sense the term "strumous inflammation" without affixing to it, as we are now prone to do, the modern idea of tuberculosis. A strumous habit of body has doubtless a marked influence in modifying other morbid conditions which may occur in earlier or later life. The specific reaction to simple irritants, giving rise to strumous inflammation of lymphatic glands, which is common in youth, may sometimes remain in the adult and extend into advanced life, and the consequences of infections, as by scarlet fever, or syphilis, or of irritation by gout, may be, and probably are, greatly modified by this tendency, giving rise to varieties in the several manifestations of these diseases. Thus, gout appears to have a tendency to linger in strumous subjects and in its articular form to be attended with greater effusion than is commonly witnessed, while chronic tubal nephritis in such subjects is apt to be more than usually grave and uninfluenced by treatment. In short, the strumous diathesis is a bad one for the incidence of most morbid conditions. Guided by our present knowledge of this condition, and of its relation to tuberculosis, we have at once suggested to us the supreme value of preventive methods in the management of strumous persons, and a *methodus medendi* for those of them who may become tainted with tuberculosis—to wit, an aseptic euvironment, good food, tonic remedies, and the free removal by the surgeon of disordered lymphatic glands. The beneficial influence of sea air has long been recognised in these cases and it led over a century ago to the institution of an admirable hospital which, though its need and usefulness are as great as formerly, has somehow been suffered to languish for want of public appreciation and support. There is still a great need for small seaside hospitals to supply the requirements of poor patients, whether scrofulous or not, from this metropolis, and a grand sphere of beneficence in this direction lies open to wealthy persons who will found and endow such institutions.

Amongst the secrets wrested from nature in recent times is the discovery of the Roentgen rays, which have already proved of great practical use to surgeons for the detection in certain parts of foreign bodies and the exact determination of injuries to the skeleton. To the physician these scrutinising rays have as yet yielded little new information. Some varieties of renal calculi may sometimes be detected by them, but they afford no evidence of biliary concretions. We may, however, obtain indications of solid tumours and aneurysms, and of enlargement of certain viscera. The therapeutic influence of these rays, if any exists, is as yet not determined. According to Rieder of Munich, rays emitted from "hard," *i.e.*, high vacuum, tubes kill bacteria. Such rays have the highest penetrating power. With the assistance of my colleague, Dr. Lewis Jones, I have examined radioscopically the lungs of several patients with tuberculous disease in various stages. The physical signs were well-marked and readily detectable by ordinary methods of examination. The consolidated portions of the lungs gave no further evidence of their condition than a somewhat dark opacity, in mottled tracts, as compared with the luminous clearness of the unaffected parts. Pleural effusions and

[24] Fothergillian Prize Essay, p. 141. London, 1846.

[25] Harvey regarded phthisis as a contagious disease and placed it with leprosy, lues venerea, and plague as "creeping through the ranks of mortal men and by mere extrinsic contact exciting disease similar to itself in other bodies." He did not believe that actual contact was necessary, since a mere halitus or miasm sufficed to cause an "univocal" like itself.—"De Gen. Animalium," Exerc. xlix. Art. "Tuberculosis," Quarterly Medical Journal, April, 1896, by Dr. Norman Moore. (Address delivered before the Medical Society of Lincoln. 1895.) It has been surmised by Dr. Archdall Reid (quoted in Dr. Arthur Ransome's Essay, awarded the Parkes-Weber gold medal of this College in 1897) that in countries where tuberculosis has existed for many generations a certain tolerance has been secured whereby resistance to the microbe has been acquired and that the inhabitants escape the full influence of the disease. Native races of other countries have possibly, he thinks, not yet acquired this degree of immunity.

[26] Dr. Parkes Weber has recently directed attention to some cases of this kind.

Digitized by Google

pneumothorax are detectable, also pneumonic consolidations, and even early and limited areas of tuberculous deposit. In a recent report on this subject MM. Bouchard and Claude of Paris [27] declare that cavities can readily be discovered and even enlargements of bronchial lymph-glands.[28] The free movements of the diaphragm are well displayed and are worthy of study, since it is found that this structure is lowered on the affected side in cases of consolidation of the apex of the lung and rendered dense and immoveable in diaphragmatic pleurisy. The most startling revelation by means of the x rays is that of M. Kelsch, who declares that he discovered the existence of pulmonary tuberculosis in 51 out of 124 military patients who presented none of the ordinary signs of the malady. With respect to these observations I will only say that I desire more detailed evidence and, with it, confirmation.

It may be affirmed that radioscopy and skiagraphs tell but little to the physician that could not be ascertained by other methods of physical examination, but they certainly afford additional means for accurate clinical determination. Thus, in a case of mitral valvular disease with great cardiac hypertrophy which I examined the melon-shaped outline of the heart could be seen to bulk more largely in the thorax than the physical signs alone led one to believe. With improved apparatus we may come to better results than any yet attained, and, indeed, there may be other secrets in the domain of electrical science awaiting diligeat research, of which perchance some may serve to revolutionise our present methods of clinical investigation.[29] Recent researches have been fruitful in respect of improved methods of vaccination and of securing the absolute purity of vaccine lymph. Our Milroy Lecturer of this year,[30] to whom is due the credit of the work, has made us fully aware of the steps by which the bacteriology of both human and calf lymph has been studied. The result has been the introduction of glycerinated calf vaccine lymph which now meets every requirement, whether demanded by the scientific bacteriologist, the medical practitioner, or the reasonable portion of the public. This discovery appears to me to open up new fields of study. The influence of glycerine in destroying some of the most noxious microbes which may gain access to ordinary vaccine lymph in various ways is very noteworthy and important, and I cannot but imagine that this agent may yet be found of more extended usefulness as a bactericide. It is surely significant that some of the most virulent germs, including those productive of tuberculosis and suppuration, should they contaminate vaccine lymph, can be completely disposed of by this simple medium within three or four weeks. We might have anticipated that such a discovery would have promptly disposed of most of the objections raised against the universal and compulsory practice of vaccination in England did we not know that ignorance and prejudice, fostered by misrepresentation and stimulated by paid agitation, require a strong hand for their repression. I speak advisedly of *repression* in a matter so vital as this, for there are varieties of ignorance and prejudice, some of which may safely be left for time and education to disperse. But here we are in face of a terrible danger with accredited succour at hand, and the *mens medica* has no hesitation as to the course to follow.

And, Sir, what I am now about to say I venture to say in my private capacity, not committing the College to the opinion, although I know that it is shared by the majority of those whom I have the honour of addressing. I refer to the recent Parliamentary treatment of the Vaccination Bill and I make bold to stigmatise it as a piece of panic legislation, a lamentable concession to ignorance, fraught with serious peril to the whole community, and unworthy of the duty and dignity of any British Government. By many of us the report of the Royal Commission on Vaccination was considered by no means too strong, but, alas, it has been left to the countrymen of Edward Jenner, by sanction of what has well been termed "a tremendous experiment," to place England, hitherto foremost in State medicine, in a humiliating position before the world. Let us try to imagine today the contempt our Harvey would have felt for the men who so treated the revelations of truth sought out from nature. Of Harvey's skill as a practical physician we have little actual knowledge. This is mainly owing to the loss by robbery and destruction of his papers, including what must undoubtedly have been a storehouse of wisdom, his "Medical Observations," to which he occasionally makes allusion in various treatises. Our art is not improbably the poorer to-day for this untoward circumstance. We know that his "therapeutique way" did not commend itself to the practitioners of his time, but we may fairly believe that his natural powers of insight, quickened by constant and accurate biological studies, suggested to him methods of treatment which his contemporaries, still held in the bondage of dogma and routine, failed to comprehend. We may, however, form an opinion as to his clinical sagacity from the following sentence taken from his second "Disquisition on the Circulation of the Blood," written to Jean Riolan: "How speedily is pain relieved or removed by the detraction of blood, the application of cupping-glasses, or the compression of the artery which leads to a part? It sometimes vanishes as if by magic." And then he proceeds: "But these are topics that I must refer to my 'Medical Observations' where they will be found exposed at length and explained." These facts are assuredly as true to-day as they were 250 years ago, but I will venture to say that they are not adequately recognised in practice at the present time, and that in consequence some of our patients do not receive the prompt measures of relief which are available for them. The fierce controversies which have raged in this century on the subject of blood-letting have had for their result a serious neglect of its appropriate application. Guided by modern physiology with its teaching in regard to the physics of the circulation, no less than by our larger knowledge of morbid conditions, we have now a full warrant for the judicious employment of a practice which has always commanded the assent of the best clinical observers.

I have barely alluded to the scientific achievements of Harvey's long life. The full scope of his original discoveries is possibly even now imperfectly realised by those who connect his name merely with the doctrine of the circulation of the blood.[31] Yet this discovery was but the final exposition of a fact, only disclosed to him after assiduous anatomical labour, directed and pondered over by his surpassing intellect. The steps which led to it slowly elicited, not only the mechanism of the circular course of the blood, but the important fact previously unknown that this fluid was uniformly diffused and common to all the blood-vessels of the body.[32] Harvey, moreover, was the first to interpret correctly the physiology of the heart. His great work on "Animal Generation," of which he was so diffident and which was, as it were, dragged from him by his admiring friend, Sir George Ent, for the purpose of publication, would by itself have raised him to the first rank of biologists, although, as Willis remarks, to complete and perfect such a task as this was impossible even for Harvey with the means at his disposal in the seventeenth century. His minor treatises show, equally with his greater ones, the same originality and intellectual power. But I will not dilate on these topics, they have been often discussed before us here. I have preferred on this occasion rather to present to you the pre-eminent qualities of the mind and character of Harvey and to indicate the wholesome lessons which they afford for us. Harvey himself best summed up his great characteristic and guiding principle in a concise sentence which might even now be fitly inscribed on his sarcophagus, and it is this: "I avow myself the partisan of truth alone." That was the great moral of his life—truth eternal, ever to be sought for, to be held and to be passed on. Let us ask ourselves if the orator of 1998 will be able to say that such was our ideal in this College at the close of the preceding century? We may fairly hope that he will not hesitate so to speak of us. In my belief nothing will better tend to foster and maintain such a standard amongst us than the disclosure year by year

[27] Congress for the Study of Tuberculosis, Paris, July, 1898.

[28] These observations have been quite lately confirmed by Dr. Hugh Walsham at St. Bartholomew's Hospital. (See THE LANCET, Oct. 15th, 1898, p. 988.—ED. L.)

[29] "Nor do I doubt but that many things still lie hidden in Democritus's well that are destined to be drawn up into day by the ceaseless industry of coming ages." (Letter to John Daniel Horst, Principal Physician of Hesse-Darmstadt. Harvey, 1654.)

[30] Dr. Sydney Monckton Copeman, a Member of this College.

[31] "The old humoral pathology has lost its roots since Harvey showed that the blood is a circulating fluid and not a parenchymatous juice."—Professor Virchow. (Address delivered at the Tercentenary Festival of the University of Edinburgh. 1884.)

[32] I remember that my esteemed teacher, Professor Goodsir, of Edinburgh, was wont to describe the blood as an organ. His successor, Sir William Turner, has confirmed my recollection and writes to me as follows: "Goodsir regarded the blood as an organ and the blood corpuscles as the tissues of the organ. His mind was so full of the importance of the cell as a force in nutrition that to him the collective cells of the blood represented an organ, although they were not fixed in their place, but moved with the blood-stream. His conception was, I believe, a true one."

in this place of the character and works of our immortal Harvey. To have had him, to be summoned regularly to peer into his great mind, to learn his methods, to be counselled by his wisdom, and to participate in the benefactions he so affectionately designed for us, constitutes, indeed, a high responsibility of which we must ever feel sensible in this his beloved College.

I have now, lastly, in accordance with Harvey's direction, "to exhort the Fellows and Members for the honour of the profession to continue in mutual love and affection among themselves, without which neither the dignity of the College can be maintained nor yet particular men receive that benefit by their admission into the College which they might expect, ever remembering that *concordia res parvae crescunt, discordia magnae dilabuntur.*" According to Willis, "every act of Harvey's public life that has come down to us is marked not merely by propriety but by grace." I venture to think that we in this College are well knit together in mutual regard and sympathy and thus maintain in these respects what Harvey desired should ever exist here. The concord which we enjoy truly preserves our dignity, for it adds weight to our deliberations and our efforts. It is a good deal the fashion in these days to deride dignity and its symbols, but wise men in all times have realised the risk which the loss of them entails, and have had cause to learn that when the symbol is dropped the reality also is only too apt to disappear. But our life work as the physicians of England is not done here. Our duties take us to serious and responsible ministrations to all classes of our countrymen. Our various positions demand that, with perfect freedom and independence, we bring our best knowledge and influence to bear on all human interests. May we indeed be careful to carry with us in all the relations of life, professional and otherwise, the tone and bearing which are demanded of all who belong to this College. May we strive to be like-minded with those whose memory we have just praised, and, not least, with the simple, unselfish, Christian gentleman before whose life work and beautiful character we have once more bent to-day in solemn admiration.

A Post-Graduate Lecture

ON

CORNEAL ULCERS AND THEIR TREATMENT.

Delivered at the West London Post-Graduate College on July 16th, 1898,

BY PERCY DUNN, F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL.

GENTLEMEN,—One of the commonest forms of disease met with among ophthalmic out-patients is that of ulceration of the cornea, but despite the frequency with which it occurs it should never be lightly regarded inasmuch as it constitutes a most fertile source of diminution of vision among the poorer classes. Ulcers of the cornea, speaking generally, are an indication of malnutrition; that is to say, the patients, both children and adults, are either suffering from the effects of overwork and under-feeding or they are markedly anæmic from some other cause. It is this depression of vitality which explains the occurrence of ulcerationof the cornea after certain of the exanthemata, such as measles, scarlet fever, and small-pox; in fact, anything which lowers the general health is prone to be followed by corneal ulceration. In curious contrast, however, with the frequency of this disease among the poor is its absence among the better classes. In private practice ulcer of the cornea is a very rare affection. Sometimes, of course, it occurs, and in this connexion I recollect a well-known surgeon telling me that during his student days he read with so much assiduity for his examinations that he at length developed an ulcer on each cornea. On the other hand, traumatic ulcers of the cornea are not infrequently seen in private practice. Only recently a gentleman was sent to me with an ulcer of this kind caused by the branch of a thorn bush. He was passing through a hedge carrying his gun when the branch suddenly flew back and struck his right cornea. The ulcer soon healed and left a barely perceptible opacity. But shortly after this he came to see me one evening with the following curious history. While dressing for dinner he somehow succeeded in injuring his left eye with the sharp edge of his shirt front, which caused him much pain. On examination there was a small abrasion of his cornea. The pain, however, was soon relieved by a few instillations of cocaine and atropine and he was able to fulfil his engagement without much discomfort.

The clinical aspects of corneal ulcers may be dealt with so far as their immediate and remote effects are concerned. Let me refer to the latter first. Inasmuch as ulceration of the cornea involves a loss of corneal tissue it necessarily follows that the process of repair must result in the formation of an opacity and the extent to which the opacity interferes with the vision mostly depends upon that part of the structure on which it is situated. If the ulceration has been marginal no loss of vision ensues, but the closer it has approached the centre—that is, the pupillary area—the greater is the interference with the sight. Sometimes it is curious to note the declension of vision associated with opacity of the cornea. A patient may come complaining of imperfect sight and on testing the vision by the distant types we find that no glass improves; then it remains for the examination with oblique illumination to reveal the cause. A faint though perfectly definite central cornea haze is found which at the time of the first examination was not apparent.

In discussing the next question—namely, that of the immediate effects of corneal ulcers—the first point to consider is the causation of the lesion, and here I think that it is quite unnecessary to embark upon an elaborate classification. The more simple one can be the better, for, after all, whatever the etiology may be the main thing is the treatment, and this, except in complicated cases, does not vary much in the majority of instances. For all practical purposes, then, corneal ulcers may be divided into (1) traumatic, (2) simple, and (3) complicated. I have assigned to the traumatic variety a distinct class inasmuch as the primary treatment which they demand differs from that of the rest. The essential detail to bear in mind with regard to traumatic ulcers is that they may be, and commonly are, infected with pathogenic micro-organisms at the time of the receipt of the injury. Clearly, therefore, it is wise to treat them antiseptically from the beginning and apply to them those principles of cleanliness such as regulate the treatment of traumatic lesions elsewhere in the body. If the ulcer has resulted from a foreign body or a scratch or from some similar cause cocaine should be instilled into the conjunctival sac and afterwards a warm chinosol solution (1 in 2000) should be douched over the eye until thorough cleansing has been secured. Atropine drops (of the strength of 2 gr. to an ounce of water) may then be instilled and a pad of chinosol gauze applied and secured with a bandage. The drops may be used night and morning and the sac washed with chinosol solution at the same time until the eye is well. Perhaps the most serious examples of traumatic ulcer which I have seen have been those in which the cornea has been scratched by the finger nail. Infants sometimes inflict this injury upon their mothers, but in one case under my care an elderly man came to the hospital whose story was that his eye had been accidentally scratched by his landlady. On examination there was a large ulcer of the left cornea in the lower and outer quadrant, and commencing hypopion. Eserine drops (½ gr. to an ounce of water) were ordered, but the case was not then treated antiseptically and only hot poppy fomentations were ordered. He was told to return in two days. At that time I found that he was complaining of much pain, the ulcer was decidedly larger and partially sloughing, and the anterior chamber was full of pus. He was admitted into the hospital; I then made a small incision through the cornea from below with a Graefe's knife and evacuated the pus from the anterior chamber, hot boric acid fomentations were applied and the eserine was continued. Under this treatment improvement quickly began and in about a week's time he was able to leave the hospital with the ulcer nearly healed. The explanation of the infectivity of these cases presumably is that the nail while inflicting a wound on the corneal surface affords the opportunity to the pathogenic micro-organisms collected under its free edge to inoculate the lesion. It is evident, then, that these and other traumatic ulcers demand careful antiseptic treatment

from the first in view of the trouble arising from their liability to septic infection.

Simple ulcers of the cornea may be described as those in which the ulceration is unaccompanied by any distinguishing feature, such as vascularity, hypopion, sloughing, &c. This form of ulcer is most commonly seen among weakly school-children. Perhaps the most troublesome symptom associated with it is photophobia, which, however, is very variable in degree. Sometimes the intolerance of light may be extensive; on the other hand, there may be very little or hardly any to speak of. At any rate, the size of the ulcer bears no relation to the intensity of the photophobia. In young children, for example, in whom acute blepharospasm has been present for some days, careful examination of the cornea under an anæsthetic may disclose an ulcer not larger than the head of a pin. Again, these simple ulcers are seen in connexion with phlyctenular ophthalmia. They are generally superficial and after healing scarcely leave any opacity in the majority of cases. Their treatment is quite simple. If much photophobia be present cocaine and atropine drops may be used twice a day and the eye at the same time bathed with warm water. A shade should also be worn with a thin layer of cotton-wool under it in order to exert some pressure upon the closed upper lid, thus keeping the eye in a condition of physiological rest. Internally a tonic should be given, nothing being so efficacious as a preparation of iron; the tincture of the perchloride with glycerine answers admirably. If the photophobia be not troublesome some atropine drops (2 gr. to an ounce of water) may alone be used, and it is useful to bear in mind that their instillation should be continued until all injection of the globe has subsided. Afterwards some dilute yellow ointment may be placed in the conjunctival sac every night at bed-time as a stimulant to the processes of repair. In the majority of cases this treatment amply suffices to effect a cure. But it is useless to expect a good result if the child be permitted to attend school. All school work should be interdicted until the eye has made a good recovery.

Complicated ulcers may be divided into the sloughing, vascular, and infective varieties. Any ulcer of the cornea may pass into a sloughing condition and when this occurs the cause is due to pathogenic infection. One of the sources of such infection is stated—and repeated—in text-books to be chronic dacryocystitis; the condition, therefore, of the lacrymal passages should always be examined into in these cases. Sloughing ulcers are not infrequently seen during lactation in weakly young women, whose anæmic, underfed condition altogether unfits them for continuing the duties of nursing their offspring. In bad cases the ulcers may be multiple and both eyes may be involved, and inasmuch as the ulceration extends into the deeper layers of the cornea perforation with prolapse of the iris may supervene and add still further to the seriousness of the destructive effects of the disease.

Coming to the question of treatment I have repeatedly found that sloughing ulcers of the cornea are best treated from the first with eserine. The strength of this drug which I use is half a grain to an ounce of sterilised water and this I never exceed. With drops of such strength no irritation is caused, while the full benefit of the drug is obtained. Practically the effect of the drops can be regulated by the frequency of their instillation. Speaking generally, two instillations a day will be found to be sufficient, but if more are considered to be advisable these can be administered without fear of pain or irritation being induced. I shall refer to this use of eserine more fully later. Again, heat in the form of hot fomentations is absolutely needful; nothing so effectually relieves the oftentimes acute pain accompanying these ulcers. The cornea likes warmth. A large pad of chinosol gauze dipped into boiling water and wrung dry should be placed over the lids of the affected eye and the applications continued for half an hour or more twice or thrice a day. A few words may now be said regarding hot fomentations. It should be remembered that belladonna in this form is best avoided. For example, belladonna fomentations are contraindicated when the eye is under the influence of eserine, for the one drug would counteract or neutralise the effects of the other. Again, it is inexpedient to use belladonna when the eye is under the influence of atropine, for the combination of the two is apt to cause atropine irritation. Lastly, a fomentation is not usually intended for the application of a drug, but as a means for the employment of heat; hence if any drug be used it is best to employ some antiseptic, as chinosol, by which the conjunctival sac will be kept as far as possible in an aseptic condition and the repair of the ulcer more directly promoted. In addition to the local treatment the patient should have good food in abundance, as well as a preparation, say, of quinine and iron, while it is very needful to remember that in bad cases occurring in connexion with lactation the weaning of the infant becomes an essential element of treatment.

A vascular ulcer is distinguished by a leash of vessels, presumably of repair, running from the conjunctival margin across the cornea to the lesion. These vessels while coursing over the cornea naturally disturb the nutrition of the epithelium beneath them and thus opacity is often the result. The opacity so remaining has been compared to a "snail track," the mark, that is, which a common or garden snail leaves in its course while moving about at night. These ulcers are generally chronic and in earlier days were regarded as very intractable to treatment. All local treatment not infrequently failed to cure them, and then there was only one other method left, which, however, seldom failed to be successful. I allude to the use of a seton. But it is now some years since I resorted to this practice. Indeed, the mere idea of such a method is repulsive in these days of aseptic non-suppurating wounds. How can any surgeon whose faith is firm in Listerism voluntarily bring himself to inflict a wound with the deliberate intention of providing for its continuous suppuration. Still, such is the effect of a seton. The more loathsome-looking the septic silk of which it was composed became and the freer it was bathed in pus the more efficient was its action supposed to be. Every time that the surgeon dragged the seton to and fro in its fistulous track, as was the custom, he introduced a fresh supply of septic matter and thus added to the suppuration. I do not know to what extent this loathsome method is still resorted to, but for the credit of our art the hope may be expressed that it has metaphorically been relegated to the lumber room of obsolete remedies where it may be allowed to remain and be forgotten. Vascular ulcers, as I have for some years repeatedly proved, are readily amenable to treatment with eserine. A short time after I first adopted this method I was asked by the then medical superintendent of one of the metropolitan Poor-law infirmaries to see a case of vascular ulcer in one of the patients under his care. The ulcer had resisted treatment for a long time and all kinds of local remedies had been tried but had failed. Nevertheless, a seton had not been used nor had eserine. However, I recommended the latter and in a short time afterwards I heard that the case was well.

The infective ulcer of the cornea, commonly called the serpiginous, is a form of ulceration which tends to spread over the surface of that structure with an infective edge suggestive of the course pursued by phagedæna of the skin which used to be seen not infrequently some years ago. The disease is very destructive and in the majority of cases calls for vigorous treatment. Commonly it has a crescentic outline and begins at the corneal margin. The corneal tissue surrounding the ulcer may or may not appear infiltrated. The progress of the disease is strongly suggestive of its micro-organic origin and it is now believed to be due to a specific diplococcus. Much pain, photophobia, and injection of the globe usually accompany this form of ulceration, and the patients are mostly men of middle age. In advanced cases hypopion, perforation, and much destruction of the corneal tissue may ensue, leaving the patient with an irretrievably damaged organ. If seen early the disease may be arrested by treatment and a good result obtained before much damage has been done. Recognising therefore its infective nature the best plan is to treat the ulcer antiseptically from the first. Cocaine having been instilled a warm chinosol solution (1 in 2000) should be allowed to play over the surface of the ulcer and the conjunctival sac thoroughly irrigated. Then eserine drops should be instilled and afterwards finely pulverised iodoform may be dusted over the corneal surface. Lastly, some chinosol ointment should be smeared over the margins of the closed lids and a pad of chinosol gauze and a bandage applied. If after trial these measures fail and it is evident that the ulcer is spreading then the following plan must be resorted to. The eye having been cocainised a drop of a solution of fluorescin must be instilled; the area of the ulceration will then appear as a bright green surface. To the surface thus delineated the actual cautery must be applied, the margins being especially dealt with. When

Digitized by Google

healing satisfactorily follows this treatment much opacity of course remains. Among out-patients these infective ulcers are, perhaps, the least common, but they are said to occur with frequency among agricultural labourers, especially during harvest time.

In the foregoing remarks it will have been observed that I have more especially referred to two drugs—namely, chinosol and eserine—and about each of these I now propose to add some further details. With regard to chinosol, concerning the advantages of which I have been repeatedly asked, I believe it to be the best antiseptic agent which is now in the market, and the longer I use it the more I prefer it and the closer does it seem to me to fulfil the requirements of an ideal preparation of the kind. There are certain reasons for doubting whether in ophthalmic surgery the principles of antisepticism are followed in the present day to the extent which their importance demands, and it is probable that the want of precision in this regard is partly due to the fact that among the multiplicity of antiseptic agents there is none which has actually found general favour with ophthalmic surgeons. The perchloride of mercury, carbolic acid, boric acid, each has its drawbacks. Each is undoubtedly useful in its way, but neither the one nor the other has ever excited sufficient enthusiasm to cause thorough antiseptic principles to prevail in the domain of ophthalmology. The importance of this matter I believe to be such that I hold sympathetic ophthalmia would be an impossible complication in eye surgery were a wound of the ciliary region to be treated from the first with every antiseptic precaution. In fulfilment of this belief I have treated within the past year several severe wounds in the dangerous zone, and in each case the eye made an excellent recovery. The results I attributed to the systematic antisepticism practised by means of chinosol. The chemical name of this drug is potassium oxyquinoline sulphonate and one of its chief advantages is the potency of its germicidal action—a fact which has been incontestably proved by bacteriological investigation. In addition, it is freely soluble in water and thus is handy for use. Moreover, it is non-caustic, does not injure the skin of the hands, does not coagulate albumin, and is non-hygroscopic. Again, it is one of the most economical preparations in the market, for owing to its potency only weak solutions of the drug are necessary. Mixed with 1 in 20 of boric acid it forms an admirable antiseptic ointment. It might, perhaps, seem that in saying all this I am praising chinosol inordinately. The fact, however, is that a lengthened experience has taught me that it is an excellent preparation, possessing advantages which in time must commend it to every operating surgeon. With respect to eserine, there is some unanimity of opinion among the authors of modern text-books on ophthalmic surgery that the drug should be avoided in the treatment of corneal ulcers. But my experience, as will have been gathered, does not accord with that view. On the other hand, I believe that the feeling which prevails against eserine in this connexion has arisen in consequence of misconception regarding its use. The great point to remember is to use it in a weak solution. The evil repute of the drug has been mainly gained by employing solutions of greater strength than were necessary. Formerly eserine drops of the strength of four grains to an ounce of water used frequently to be prescribed, and then troublesome symptoms were nearly always induced. But it is seldom, if ever, necessary to resort to a higher strength than half-a-grain to an ounce solution, and for continuous instillation in cases of chronic glaucoma even a less strength than this may be satisfactorily employed. Experience has fully demonstrated that there are certain forms of ulceration of the cornea which atropine fails to benefit but which, on the other hand, readily yield to eserine. To define what these particular forms are is a question which has been repeatedly asked in my out-patient room and the answer may here be given as follows: all sloughing, infective and vascular ulcers are best treated with eserine as well as, of course, those situated at the corneal margin at which perforation is threatening. This may be regarded as a broad rule for guidance, but there remain other cases concerning which no rule can be expressed in words. I have in my mind those cases of simple ulcer in which atropine has been used and apparently failed. In many of such I have found eserine to act like a charm, the injection of the globe quickly clearing up in consequence and the ulcer rapidly beginning to show improvement. A typical case may here be mentioned. A short time ago a man wearing a shade was led in to my out-patient room by his wife. The history was that he had been under treatment at an ophthalmic hospital for five weeks. There was a superficial central ulcer of each cornea with photophobia and some injection of the globes. The pupils were widely dilated from atropine. This seemed to be a case in which eserine was clearly indicated. Accordingly eserine drops (½ gr. to an ounce of water) were ordered to be instilled twice a day. At the end of the week when the patient again presented himself the improvement was very manifest. Two days after using the drops the patient discarded the shade and the photophobia had gone as well as the injection of the globes. Before the end of another week he had returned to his work. Undoubtedly in cases where photophobia is troublesome eserine is of service by contracting the pupil and cutting off light to the eye, while atropine increases the trouble by dilating the pupil, thus placing the patient with his damaged cornea in a helpless condition in the presence of light beyond a low degree. It is quite possible that the utility of eserine in the treatment of corneal ulcers is partly due to the fact that the drug reduces the tension of the globe. This is only a reasonable assumption when we recollect that atropine tends to raise the tension and that an eye in which increased tension has occurred is not one in which healthy nutrition is likely to be present. By lowering the tension, then, in these cases just the difference may be made in securing the establishment of those nutritional changes necessary for the complete repair of the ulcers.

A CONTRIBUTION TO THE PATHOLOGY OF INFECTION BY THE PNEUMOCOCCUS.

BY W. H. BRODIE, M.D. ABERD.,
W. G. ROGERS, M.D., M.S. LOND.,
AND
E. T. E. HAMILTON, M.D., M.S. LOND., F.R.C.S. ENG., B.SC.

IN 1894, in a paper read before the Transvaal Medical Society under the title of "Acute Specific Rhinitis," we communicated the result of an investigation we had made on an epidemic which had occurred amongst the Kaffirs employed in one of the mines here. At least 100 cases came under our notice. These were mostly of a mild form; many, however, were severe; and out of 15 deaths we were able to perform 9 post-mortem examinations. The salient features of the disease were purulent discharge from the nostrils and, in a large majority of the cases, pneumonia. Our special attention was first drawn to this epidemic by the sudden and unexpected deaths, unaccounted for by any premonitory constitutional disturbance or signs of sufficient local disease, even when pneumonia was present.

In order to lead up to our recent work a recapitulation of our previous inquiry is desirable. A summary of the post-mortem examinations is as follows. In 1 case we found purulent meningitis and pneumonia, with a large quantity of pus bathing the mucous membrane of the nasal cavities and filling the sinuses and ethmoidal cells. This Kaffir had worked seemingly well on the day of his death; he was quite conscious and could articulate up to within a few hours of his death. In 2 cases we found meningitis without pneumonia, with a small quantity of pus in the nasal regions and sinuses. One of these patients had worked on the day of his death; the other had only complained of feeling ill for a day or two. In 2 other cases there was pneumonia without meningitis and a very large quantity of pus in the nasal sinuses and fossæ. In 1 there was slight pneumonia without meningitis and nowhere was there pus formation. This Kaffir had complained of pain in the head and loins for three days before he was seen; twelve hours before death he showed great constitutional disturbance. His temperature was 104° F. and his pulse was 130. He was sensible. Incessant vomiting set in and he gradually became comatose and there was incontinence of urine and fæces. We expected to find cerebral lesions, but they were absent. In one case we found neither meningitis nor pneumonia, and in this case again the constitutional disturbance was grave; the patient had lain unconscious for three days with incessant vomiting. In all the above

Digitized by Google

necropsies we found one condition present—a livid, injected, swollen condition of pituitary membrane. One especially interesting post-mortem examination was made. This was on the emaciated corpse of a Basuto, aged about forty-five years, who had been sent to hospital suffering from double pneumonia. He had had purulent nasal discharge and injected and livid-coloured mucous membrane over the turbinate bones. The double pneumonia was extensive, but the constitutional disturbance was slight in comparison. The temperature fell to normal on the eighth day. Sixteen days after admission he had a severe attack of dysentery which lasted about a week. When discharged a month after admission he was well except that dulness persisted over the bases of the lungs. He died a month after leaving hospital; the immediate cause of death was epistaxis. At the post-mortem examination some recent pneumonia was found at the apices, also some old consolidation going on to gangrene, but the condition of the nasal cavities chiefly arrested attention. The whole of the diseased mucous membrane had exfoliated in the form of sloughs, leaving a pallid surface; the mucous membrane of the sinuses was pale and thin, and parts of the ethmoidal cells were denuded of mucous membrane and periosteum. The apertures were remarkably patent. In one or two places the sloughs still adhered, with petechiæ in their neighbourhood. We sent 9 cases to hospital; all of the patients had red and turgid mucous membrane of the nose with more or less discharge and increased temperature; 6 had pneumonia with an abundant fine frothy expectoration—in one case four pints in twenty-four hours; 2 had no pneumonia. Jaundice was a marked feature in some of the cases and it was present in 2 at the post-mortem examinations. There was no evidence of disease of the nervous system in any of the hospital cases and they all recovered except the one case already alluded to. None of them had great constitutional disturbance, not even those with severe pneumonia. From a study of this epidemic we came to the conclusion that it was the result of a poison circulating in the blood, infecting first the nasal region and causing death by the toxæmic state which it produced, the meningitis and pneumonia being secondary and accidental—the result of the poison circulating in the blood.

Since the occurrence of that epidemic we have had many sporadic cases and have performed several necropsies, meeting the same characteristics, but there had been no serious outbreak until about six months ago, when the increased working of the mine demanded a large number of fresh hands. During the last four months about 800 raw Kaffirs came in batches into a new, commodious, and well-cared-for compound and among these new arrivals another epidemic occurred. They were nearly all of poor physique and came from the neighbourhood of Inhambane on the east coast, 100 miles north of Delagoa Bay, thence by train four days to Johannesburg, including a day's stoppage at the border to obtain passes. They suffered severely from sea-sickness and according to their report began to get ill with coughs on leaving the steamer. The winter had been exceedingly cold and they must have suffered severely from the low temperature, travelling insufficiently clad from the sea-coast to this high altitude. In fact, the only protection each had against it was a cotton handkerchief. Like their fathers for generations, at home they did no work, living on wild vegetables, sugar-cane, plantains, and occasionally the flesh of wild pigs and a little milk. After a short but trying journey they arrived from a warm and comparatively moist sea climate to this high, dry, and cold one to work in a mine 1000 ft. below the surface, their diet consisting of an unlimited quantity of mealie meal varied with fresh meat, and a supply of lime-juice. Their powers of resisting disease must have been considerably weakened by this sudden change in their habits, diet, and surroundings. A large majority on arrival were suffering from nasal catarrh and coughs, with pneumonia in one or two cases, but whether this was due to the specific organism infecting them before arrival or only acting as one factor in predisposing them to the attack here we have not yet been able to determine. During the months of June and July, the coldest months, the average number off work was about 100. They appeared to be suffering from ordinary colds complicated in various cases with pneumonia, dysentery, diarrhœa, parotitis, and in two cases with meningeal symptoms. Out of the total number of sick 40 died, and we were able to obtain 17 post-mortem examinations

One batch of 93 emaciated Kaffirs arrived in the beginning of July, when the temperature, except for a few hours during the day, persisted below freezing point; a fortnight later only 16 were working and some of them were ailing. Altogether of this batch 8 died. Owing to our being now able to pursue our study into the bacteriology of the disease we have advanced a large step towards its elucidation, and although we were unable to make bacteriological examinations in the first epidemic a comparison of the clinical and pathological characteristics of the two outbreaks leaves no doubt that they were due to the same cause. The only differences were that in the first epidemic there were several cases of jaundice and only 1 with dysentery, and this only exemplifies what we wish to emphasise—i.e., how protean the manifestations of the disease are. At first sight it was natural to suppose that the various cases of pneumonia, dysentery, parotitis, diarrhœa, and spinal meningitis were distinct and independent illnesses brought on according to the idiosyncrasy of the individual by his being unable to withstand the new conditions of life. We performed post-mortem examinations on cases in which each of the above conditions was the immediate cause of death and the pathological and bacteriological examinations proved that we were dealing with only one disease. In our former paper we gave each case in detail, its history and clinical features, as far as we were able to observe them, and the post-mortem appearances, showing the charts with notes of the cases treated in the hospital. We think it superfluous, even if space allowed, to describe *seriatim* each of the numerous cases of the later epidemic. We shall therefore only enumerate the various symptoms.

The most prominent symptoms were nasal catarrh and coughs. The compound was sonorous with coughing. This was unaccompanied by signs of bronchitis or lobular pneumonia, but in a great many cases, even when the men were at work, it was associated with lobar pneumonia. Although all cases of nasal catarrh may not have been specific, yet as a diseased condition of the mucous membrane of the nose was found in all the necropsies it is fair to assume that the large majority were due to specific rhinitis. The same can be said of the pneumonias. In nearly all the necropsies pneumonia was found and proved to be of specific origin; there can therefore be little doubt that the majority, if not all, of the cases were due to the same cause. Indeed, to reason otherwise would mean that the disease we are considering is invariably fatal—that only the 40 dead were attacked by this specific organism. The mere presence of pneumonia was not a dangerous symptom. In the large majority of cases in which it was present it involved only a small part of the lung, generally at the bases, and the Kaffirs contentedly worked with lungs in this condition. In cases in which the lungs were extensively invaded recovery took place and only in one necropsy was the pneumonia found of sufficient extent to account for death. There was always coexisting pleurisy. Parotitis was a common symptom, but, like pneumonia, was not a guide to prognosis. Diarrhœa, not noted in the previous epidemic, was prevalent. It was not of a severe form, but it was of serious import, because in some of the cases the motions gradually assumed a dysenteric character and in all of the cases in which there was dysentery which came under our notice the patients died. In the great majority of the fatal cases dysentery was the immediate cause. A characteristic of this phase of the disease was that the evacuations towards the end of the illness became entirely hæmorrhagic, mostly dark-coloured, sometimes black, and simulating the motions found in purpura hæmorrhagica. When they were of this nature they were passed involuntarily. No treatment was of avail in lessening or modifying the discharge. The following case shows that when dysentery is the pronounced symptom there is a tendency to hæmorrhage in other organs.

A Kaffir had worked for two weeks after arrival without complaining of feeling ill; he then came into the mine hospital seemingly suffering from ordinary dysentery. A few days after admission dulness with tubular breathing developed at the bases of the lungs, but there was never a large area involved. He was never heard coughing or seen expectorating. The motions, at first of the usual dysenteric type, gradually became hæmorrhagic and twelve hours before death he was passing involuntarily large quantities of very dark-coloured blood. He had no signs of disease of the nervous system. At the post-mortem examination the mucous membrane of the nose was found to be less altered than usual. Parts of the lung at the bases had red hepatisation. An abscess in

Digitized by Google

the wall of the sphenoidal sinus, pus in other sinuses, and hæmorrhagic cerebral effusion were found. Considered as a symptom of the disease, cerebral meningitis could almost be excluded. We had only two cases with well-marked signs of meningeal mischief and in both spinal meningitis was found post mortem. This latency is remarkable when we think of the number of cases in which we found extensive purulent cerebral meningitis at the necropsies; it was almost as often found as pneumonia.

We suggested in our former paper that the brain of the uncivilised Kaffir may be less responsive to disease than that of the white man, but the lung mischief showed the same latency; we only knew of its presence in most cases because it was easily discoverable by physical examination. It has yet to be decided whether this latency is due to a peculiarity of the disease or of the individual. Before entering into the pathology and bacteriology we will draw attention to a case which illustrates the latency of the meningitis and how easy it is to miss the diagnosis of the disease.

A Kaffir was absent from work for two weeks suffering from painful swollen legs; he was only seen two days before death and then only perfunctorily examined. Scorbutus was suspected. He never appeared very ill and an hour before death he was seen sitting before the fire joining with animation in a conversation. He must have then methodically rolled himself in his blanket near the fire, for he was found dead in this condition. He had died quietly. At the post-mortem examination the femoral veins were full of thrombi. There were general purulent cerebral meningitis, slight pneumonia, and the usual condition of pituitary mucous membrane.

Another case illustrating the acutely toxic nature of the disease was that of a fine Kaffir who had only been in the compound a week. He had not been working. For two days before death he had complained to his friends of feeling sick, but on the day preceding his death he said he was better and announced his intention of going to work on the morrow. He was found dead in the middle of the night. The following is from the notes of the post-mortem examination made ten hours after the death. The face was swollen. There was emphysematous crepitation along the course of the large veins. There was a bloody nasal flux. The nasal mucous membrane was swollen and livid. There were from seven to eight ounces of hæmorrhagic pericardial effusion almost black. Red hepatisation was present at the upper part of the lower lobe of the left lung; there was no consolidation of the right lung. There was recent pleurisy on both sides. The spleen was enlarged and very soft. The muscles showed marked post-mortem staining; the blood was tarry throughout the body. There was neither jaundice nor meningitis. The bacteriological examination in the three cases cited showed that they were the result of acute general infection by the pneumococcus.

Morbid anatomy.—The 26 necropsies made in the course of our investigations were in all cases commenced by sagittal section of the skull. The thoracic and abdominal viscera were examined in every case, and the spinal cord in 5 cases. The morbid conditions observed were noted at the time of examination and the present account is a *résumé* of those notes. The necropsies were made as soon as possible after death and in many cases the bodies were still warm. Many of the examinations had to be conducted within the walls of a mine compound and it is of some psychological interest to record the fact that the Kaffirs viewed our operations with favour, pleased with the idea that we were seeking "strong medicines" to heal them in their sickness, which, indeed, was ultimately if not primarily true. Their own habit is in accordance with this conceit, for they are accustomed to lay under tribute to this end the lions or other large game which they succeed in killing in their native districts. They subsequently, however, resented our taking organs for preservation from emaciated subjects.

In all the cases after death we observed a greenish, thick, purulent discharge coming from the nostrils. In many cases emission of semen had occurred about the time of death. The nasal mucosa, including that of the adjacent sinuses, showed every stage of inflammation. We found œdema, hyperæmia with purple colouration, purulent infiltration, and ulceration. In more chronic cases there was atrophy to such an extent that the tissue was pallid and the various apertures leading from the nasal fossæ were abnormally patent. This appearance was specially marked at the orifices of the Eustachian tubes, the margins of which were in these instances remarkably sharp and pallid, being covered by the thinnest of mucous membranes. On the contrary, in other cases so great was the thickening that these openings were obscured by tumour-like masses. In many of the cases the bones forming the walls of the nasal fossæ were bare and necrotic. Sloughs were observed in the vault of the pharynx and on the upper turbinated bones. In one case the walls of the sphenoidal sinus were quite denuded of muco-periosteum. Indeed, this sinus in the majority of the cases showed severe changes, being generally filled with gelatinous, greenish pus, or exhibited a collection of pus between the periosteum and the bony wall. It was always gravely implicated in the meningitis cases. The same conditions were observed in the frontal sinus and in the other air spaces communicating with the nose. Within the skull cavity purulent infiltration of the arachnoid and pia mater extended backwards, usually from the optic groove, or in some cases from the crista galli to the foramen magnum; from the base it spread over the convexities to involve the mesial surfaces of the hemispheres. The pus was seen in the processes of the pia mater dipping into the sulci and followed the reflexion covering the choroid plexus of the lateral ventricle; the membrane in this position was thick with œdema. Over the cribriform plate of the ethmoid in some cases the meningitis was especially marked; also along the ophthalmic veins at their entry into the cavernous sinus. The cranial nerve-sheaths of the first eight pairs were often profoundly affected; sometimes the intracranial part of the optic nerve was obscured by the exudation. The under-surface of the pons was involved in some instances and in both of the spinal cases. The cerebellum usually escaped. In one case referred to in the clinical part of this paper, we found hæmorrhagic effusion into the choroid plexus and velum interpositum; in the subarachnoid cisterna between the posterior surface of medulla and cerebellum; also in the fourth ventricle and on the ventral surface of the pons round the basilar artery. In 1 case examined otitis media was associated with the rhinitis and meningitis. Spinal lepto-meningitis was found in 2 cases out of 5 in which the cord was examined. In 12 cases out of 26 meningitis was present. The exudation in some cases was jelly-like, homogeneous, and clear both in the spinal and cerebral meninges. In others, however, the inflammatory material present was fluid rather than jelly-like, opaque and granular rather than clear; and we surmised at the time that these latter characters might be dependent upon the presence of the commoner pyogenic organisms in addition to that of the specific diplococcus.

The condition of the lungs and pleura varied; croupous pneumonia was present in the majority of the cases, but in a few the lungs were healthy. All stages of the pneumonic process were represented, from congestion to gangrene, and the extent of lung involved differed within very wide limits. Recent pleuritic lymph always accompanied the pneumonic consolidation. Effusion into the pleural cavity was often present but never exceeded a few ounces. In no case was endocarditis found. The pericardial sac contained excess of fluid in the majority of instances; the great vessels often showed excessive post-mortem staining. In one case œdema of both legs was noticed during life, and on examining the common femoral veins ante-mortem coagula were found. The peritoneal cavity usually showed a considerable amount of fluid. Perihepatitis and perisplenitis were marked features in one case, in which, however, there was also extensive recent pleurisy on both sides accompanying red hepatisation; the spleen weighed 12 oz., and both it and the liver were firmly adherent to the diaphragm. The infection was obviously general, for both cerebral and spinal meninges were involved. We examined the joints in some of the cases, always with a negative result. Double parotitis was observed once. In those cases in which dysenteric symptoms had been present no gross change was seen on inspection of the intestine and the mesenteric vessels appeared to be healthy. A question of interest is the inquiry as to the path taken by the organism from the nose to the brain and other viscera. As a result of our examinations we think the most usual course to the interior of the skull is from the muco-periosteum of the sphenoidal sinus to the sheaths of those nerves embedded in the wall of the cavernous sinus and thence by direct extension to the arachnoid and pia mater. In other cases undoubtedly the organism infects the meninges by extension along the nerves or vessels traversing the cribriform plate of the ethmoid; for it has been shown that the nasal lymphatics are in communication with the subdural and subarachnoid spaces by

Digitized by Google

means of perineural paths. Another possible route is by the Eustachian tube to the middle ear and petrous bone, thence by the seventh and eighth nerve sheaths.

The parotid glands are possibly infected from the mouth, though we think it more likely that they share the general infection when that is established. The lungs suffer in the same event, but probably sometimes by direct extension along the respiratory tract. We arrived at this conclusion from the rarity of antecedent laryngitis, tracheitis, or bronchitis, from the general distribution of the specific organism throughout the body, and from the character of the pneumonia, which was lobar, basal, and fibrinous. We remember having seen some years ago in the post-mortem room, several cases of purulent meningitis in which a primary focus of suppuration was diligently sought for without success. We remember one case in particular, that of a man who had twenty-four hours before admission first evidenced illness in change of conduct and sentiment. He died next day and on inspection suppurative meningitis was found without any apparent source of infection. We are inclined to believe that a bacteriological examination of the pus in this case would have revealed a pneumococcal infection.

Pathology —Fifteen cases were subjected to a complete bacteriological examination. 1. In every case cultivations were made on gelatin, agar agar, blood agar, and in broth. These were taken (*a*) from the pus in the nasal fossæ and in the nasal, frontal, sphenoidal, ethmoidal and superior maxillary sinuses; (*b*) from the purulent exudate in the arachnoid, cerebral and spinal; (*c*) from the fluid in the cerebral ventricles; (*d*) from the pericardial, peritoneal, and pleuritic fluids; (*e*) from the heart blood and blood in the cranial venous sinuses; and (*f*) from the lungs, kidneys, and spleen. In all cases we were careful to exclude the possibility of infecting our cultures by using the hot iron freely and subsequently making incisions with sterilised instruments. We were also fortunate in being able to conduct the bacteriological examinations very soon after death.

In our cultivation experiments we obtained the organism described below in pure culture from either the spleen, the pericardial fluid, or the heart blood of 7 cases. In some of the cases we obtained the organism in pure culture from all three sources named. In the remaining 8 cases we obtained no organisms of any kind in these (pericardial, heart blood, and spleen) tissues in our cultures (one tube inoculated from each). In 2 cases we obtained pure cultures of the organism from the cerebral exudate, in 5 others examined it was associated with streptococci and staphylococci. The characters of the organism thus obtained are as follows.

Morphology.—Microscopical examination showed the pure cultures to consist of lanceolate micrococci, nearly always united in pairs and tending in old cultures to grow into chains, rarely occurring as single cocci. In recent cultures, particularly on blood agar, the cocci are surrounded by a transparent halo-like capsule which is most obvious in coverslip preparations from the recent tissues and which disappears in cultures on any media. Since the organism most commonly occurs as such we have called it a diplococcus throughout this paper. It stains well with aniline colours and by Gram's method. The capsule is also well seen after double staining with methylene blue and eosine.

Biological characters. — The diplococcus grows in the presence of oxygen. It is not motile. We find that it grows best in media having a slightly alkaline reaction and that the capsule is retained longest when the organism is grown on blood agar prepared according to the method advocated by Dr. Washbourn and Dr. Eyre, of London. Of its growth on gelatin we would prefer to reserve our opinion. Our experiments were made in the autumn and the room temperature very often varied 20° F. in the twenty-four hours. Once or twice we thought we were getting a growth on gelatin but we were never satisfied on this point. In broth it grows well, rapidly producing a cloudiness throughout the medium. In this medium we found that the organism was still pathogenic for rabbits at the end of four days. Upon blood agar the diplococcus forms minute, almost colourless colonies at the end of from twenty-four to forty-eight hours. Numerous coverslip preparations were made from the fresh tissues in every case and from the same sources from which cultures were taken. Microscopical examination of these coverslips showed the presence of the diplococcus which we have described throughout the body. In 9 of the cases we found this organism and no others in the heart blood, the pericardial fluid, and the spleen. The preparations taken from the nasal fossæ were, of course, always very mixed, but even in these the diplococcus was in great excess. In the pus from neighbouring sinuses various organisms were found, but here next to the diplococcus the most numerous organisms were streptococci and staphylococci. In the purulent exudate involving the arachnoid in 8 cases we found only the diplococcus; in the remainder streptococci and staphylococci were associated with it. From our microscopical examinations it seemed that the diplococcus first invaded the cerebral tissues, followed very speedily by the streptococci and staphylococci. In the two cases in which we examined the spinal arachnoid only the diplococcus was present. Preparations from the lung were always very mixed, but as before the diplococcus was in great excess. In the kidneys and the liver the diplococci were not as numerous as in the spleen.

Inoculation experiments.—Cultures and spleen juice injected into the peritoneal cavity of rabbits killed the animals in from twelve to forty-eight hours. After inoculation the temperature of the animal speedily rose to from 3° to 5° F. above normal and continued so until shortly before death, when it usually fell. Post-mortem examination showed an œdematous infiltration of the cellular tissues, chiefly about the seat of inoculation, while small hæmorrhagic spots were common throughout the body, the whole appearances being exactly as we had seen them in Dr. Washbourn's laboratory at Guy's Hospital after inoculation with the pneumococcus of Fränkel. In the spleen, the heart blood, and the œdematous infiltrations in these animals we found the diplococcus in immense numbers and again obtained it in pure culture. We also injected a virulent blood agar culture into the subcutaneous tissue of the neck of a horse. Six hours later the animal appeared to be very ill. The temperature was 107° and the respirations were from 50 to 60. He refused his food and continued in this condition for five days, when the temperature fell, his appetite returned, and he slowly recovered after an abscess had formed at the seat of inoculation.

Conclusions.—From these observations and experiments we conclude:—1. That the diplococcus we have described is identical with the pneumococcus of Fränkel but that probably it is of a more virulent type. 2. That the pneumococcus is the specific factor in the causation of cerebro-spinal meningitis. 3. That in these cases the pneumococcus first affects the nasal mucous membrane and produces there a definite local lesion (rhinitis), and that all other subsequent pathological effects—infection of frontal and nasal sinuses, middle-ear suppuration, parotitis, pneumonia, meningitis, &c.—are merely the result of the extension of the organism along various anatomical channels of infection—e.g., continuity of tissues, lymphatics, and blood-stream. The post-mortem appearances of the nasal region which led us in our first observations on this disease, before we had made any bacteriological investigations, to name it acute specific rhinitis will serve to show how strongly we were convinced of its local origin. 4. That a pneumococcic septicæmia the result of a pneumococcic rhinitis, even when unattended by such secondary effects as pneumonia or meningitis, is sufficient to cause death. May not this explain the "fulminating attacks" of epidemic cerebro-spinal meningitis of previous writers? It is interesting to compare the pathology of the disease under consideration with that of infection by the bacillus tuberculosis. In the latter the presence of a definite bacillus in every case of attack, whether the field be lung or brain, proclaims the specific nature of the invasion. We think that the observations here recorded are simply further illustrations of the multiform effects produced in the body by the life activity of an equally definite micro-organism and that further research will establish the contention that a general infection by the pneumococcus with its diverse lesions is often the complement of an unsuspected acute specific rhinitis.

In drawing this communication to a close we are conscious that there are many points which yet require attention and which we feel confident will throw further light on the apparent vagaries of this striking disease. We have been unable, for instance, to work out the history of the not infrequent presence in the cerebral meninges of streptococci and staphylococci, but from the fact that we have never found these organisms in the blood, the spleen, or the tissues we are inclined to the belief that they invade the brain only after the pneumococcus has prepared the way—an opinion which microscopical results appear to confirm. Neither have we had time to trace by means of histological sections the course of the pneumococcus from the nose to the brain. We have as yet done no work on immunity, but we

Digitized by Google

hope that the high virulence of this pneumococcus will facilitate the preparation of serum which may be efficient in cases of ordinary "pneumonia" as occurring in Europeans. In excuse for these many shortcomings we can only say that the present work was carried out in the spare time snatched from our private practices, and that we feel constrained to publish our results thus early in the hope that other observers will establish our chief contention that infection by the pneumococcus is primarily a purely local phenomenon.

Johannesburg, South Africa.

THE USE OF FORMALIN LAMPS FOR THE DISINFECTION OF ROOMS (ALFORMANT LAMPS AND FORMOGÈNE RICHARD).

BY A. A. KANTHACK, M.A., M.D. LOND., F.R.C.S. ENG., F.R.C.P. LOND.,

FELLOW OF KING'S COLLEGE, CAMBRIDGE; PROFESSOR OF PATHOLOGY, CAMBRIDGE UNIVERSITY.

(From the Pathological Laboratory of the University of Cambridge.)

THE disinfection of rooms, furniture, and bedding is a matter of great importance to all general practitioners and especially to those who live in the country. It must be the desire of all to possess a method which is both simple and certain and, at the same time, not destructive in its action. Numerous papers have appeared recently which have occupied themselves with the question of the disinfecting power of formalin vapour. It is generally allowed that formalin vapour is a powerful disinfectant and it therefore promises to replace those gaseous substances which have hitherto been in use and of which some are useless and others injurious to man and the objects around. Lately simple and complicated forms of apparatus have been designed for the rapid and continued production of formalin vapour, and these by their manufacturers have been recommended as being unfailing in their disinfecting action. Writers abroad, however, are gradually recognising the limitations of the formalin process and there is now an almost general consensus of opinion that formalin in the manner in which it is produced by almost all the different apparatus in use has only a limited power of penetration. There is no necessity for me to survey the extensive literature upon this subject of disinfection of rooms by means of formalin vapours, since it may be found in almost any recent volume of the *Centralblatt für Bacteriologie* and the *Zeitschrift für Hygiene*.

In this country three formalin lamps are in use, and having been frequently asked regarding their respective value I undertook a series of experiments in order to satisfy myself on this point, especially since others have already spoken with unveiled enthusiasm of these lamps. The Formalin Hygienic Company supply two simple apparatus—viz., the Alformant Lamps A and B; and the Germicide Disinfecting Association a somewhat more complicated lamp, the Formogène Richard Lamp. In this paper I propose to describe a number of experiments which were made under laboratory conditions with the purpose of independently testing the efficiency of these three lamps, which all profess to accomplish similar results. By means of laboratory experiments, however, we can only decide under what conditions formalin vapours are likely to act; the final verdict must be pronounced when an apparatus has been tested under practical conditions. The principle of the Alformant lamps depends upon the conversion of solid paraform into active formalin gas by means of heat in the presence of water and carbonic acid. Alformant Lamp B is a small, toy-like apparatus, and it is stated in the directions for use that one tablet of paraform is required for the ordinary sterilisation of 1000 cubic feet of air and ten tablets are required for thorough disinfection and certain destruction of all pathogenic germs in 1000 cubic feet of space, whether these be scattered about superficially or hidden in bedding, stuffed seats, books, &c. Alformant Lamp A is merely a larger model; otherwise it is said to act in exactly the same manner as Alformant Lamp B. In the Formogène Lamp the formalin is obtained by means of the incomplete combustion of strong wood spirit. It is unnecessary for me to describe the mechanism of the lamps and I shall at once proceed to state my results.

1. *Alformant Lamp B (small pattern).*—Two sets of experiments were made and in each case 25 tablets were burnt. A room was used, the windows, fireplace, and other openings of which were carefully closed and sealed, so that little or no formalin could or did escape. It has recently been stated that such stringent precautions are not necessary, but it seemed advisable under the circumstances to prevent any loss of the formalin vapour. The measurement of the room was 18 ft. by 12 ft. by 9 ft.—that is, its capacity was well under 2500 cubic feet, so that, according to the instructions, 25 tablets should have amply sufficed for complete disinfection. As test objects I used small strips of linen which had been dipped (1) in 24 hours old broth cultures of anthrax bacilli; (2) in 24 hours old broth cultures of typhoid bacilli; (3) in 24 hours old broth cultures of staphylococcus pyogenes aureus; (4) in sewage effluent; and (5) in an old typhoid stool. These were subsequently dried over sulphuric acid at 38° C. The dust of the room also served as a test object and animals were placed in the room during the experiment. The strips were distributed in the room at different places, some openly exposed on the benches and on the floor, others wrapped up in ordinary dusters. After 24 hours the room was opened and the strips at once dropped into broth, and the latter was then incubated at 38° C. The results of these 2 experiments are given in tabular form.

Experiment I. (Alformant Lamp B).

Test material.	Exposed on table or floor.	Wrapped in dusters.
Linen strips dipped in sewage	+	–
Linen strips dipped in a typhoid stool	+ –	–
Linen strips dipped in culture of typhoid bacillus	+	–
Linen strips dipped in cultures of anthrax bacillus	+	–
Linen strips dipped in culture of staphylococcus pyogenes aureus	+	–
24 hours old culture of anthrax bacillus on agar-agar	–	–
Dust	+ –	...

+ = completely sterilised; – = not sterilised; and $\frac{+}{-}$ = sometimes sterilised, at other times not sterilised.

We learn from this experiment that only the most superficially exposed material was disinfected and that the formalin failed to penetrate even through thin dusters.

A second experiment was arranged in exactly the same manner, 25 tablets being used as before. In this case all the linen strips, whether superficially exposed or not, had escaped the action of the formalin, so that this experiment was altogether negative, although all possible precautions had been taken.

Experiment II. (Alformant Lamp B).

Test material.	Exposed on table or floor.	Wrapped in dusters.
Linen strips dipped in sewage	–	–
Linen strips dipped in typhoid stool	–	–
Linen strips dipped in 24 hours old broth culture of typhoid bacillus... ...	–	–
Linen strips dipped in 24 hours old broth culture of anthrax bacillus	–	–
Linen strips dipped in 24 hours old broth culture of staphylococcus pyogenes aureus	–	–
24 hours old agar-agar culture of anthrax bacillus	–	–
Dust	–	...

In this experiment disinfection failed completely.

It is evident, especially when we also consider Experiment I., that Alformant Lamp B is uncertain in its action and therefore untrustworthy. Hence this lamp, however

Digitized by Google

tempting in its modest simplicity it may appear, cannot be used for the disinfection of rooms, for certainty in its action must be a necessary condition.

2. *Alformant Lamp A.*—Having obtained such unsatisfactory or at any rate untrustworthy results with the smaller lamp I took the large Alformant Lamp A and using 50 tablets on this occasion I arranged the experiment almost exactly as the previous ones.

Experiment III. (Alformant Lamp A).

Test material.	Exposed on table or floor.	Wrapped in dusters.
Linen strips dipped in 24 hours old broth cultures of typhoid bacillus	+	-
Linen strips dipped in 24 hours old broth cultures of anthrax bacillus	+ -	+ -
Linen strips dipped in 24 hours old broth cultures of staphylococcus pyogenes aureus	+	+
Linen strips impregnated with spores of the hay bacillus	-	-
Dust	-	...

The previous experiment was repeated with the Alformant Lamp A, using again 50 tablets. The result was as follows:—

Experiment IV. (Alformant Lamp A).

Test material.	Exposed on table or floor.	Wrapped in dusters.	Placed in small book.	Placed in a blanket.*
Linen strips dipped in 24 hours old broth cultures of bacterium coli	+	-	-	...
Linen strips dipped in 24 hours old broth cultures of anthrax bacillus	+	+ -	-	-
Linen strips dipped in 24 hours old broth cultures of staphylococcus pyogenes aureus	+	-	...	-
Linen strips impregnated with spores of the hay bacillus	-	-	-	-
Linen strips dipped in typhoid stool	-	-	-	...
Dust in room	-	...	...	...

* The blanket was hung over a cord and the strips were placed between the two layers.

We learn from these experiments that Alformant Lamp A is almost as uncertain in its action as Lamp B, that at best it only affects the most superficial organisms or materials, that it has little or no penetrating power, and that a single sterilisation is certainly insufficient.

It is difficult to explain how others, in this country especially, succeeded in getting better results; in my hands, however, numerous failures had to be recorded, so that although the lamp is infinitely better than SO_2, as ordinarily applied, it is not trustworthy enough for practical use when employed as indicated in the "directions for use." It may be mentioned that animals left in the rooms during the experiment invariably survived.

3. *Formogène Richard.*—Preliminary experiments showed that with a single lamp the results were uncertain and therefore I performed three complete experiments, using two lamps. In this case the odour of the gas which is given off is much stronger than is the case with the Alformant lamps, so that the cultivations at the end of the experiments were always made under considerable personal suffering on account of the strong irritant action of the gas, which made a prolonged sojourn in the room impossible. Animals left in the room during the process of disinfection invariably died, so that undoubtedly we are here dealing with a much more powerful gas. The following results were obtained:—

Experiment V. (Formogène Richard—2 lamps).

Test material.	Exposed on table or floor.	Wrapped in dusters.	Placed in a small book.	Placed in a blanket.	Placed in a covered glass dish.	Placed in a bundle of cotton wool.

In this experiment the results were not quite so good or certain as in the previous cases and probably this was due to the fact that much of the formalin vapour escaped through the open flue.

Experiment VIII. Effect upon fæcal stains and blood-stains.—Experiments were also made as to the effect of formalin vapour on fæcal stains or blood-stains. It is important to know whether such stains are rendered indelible or not, for if they are it is obviously impossible to disinfect sheets or other materials soiled with fæces or blood without previously washing them. It was found that, as has already been shown by others, handkerchiefs stained with blood or fæces, although completely sterilised by the vapours produced by two Formogène Richard lamps, are ruined, because no amount of washing afterwards will remove the stains. It is therefore impossible to use formalin vapours for the direct disinfection of linen soiled with fæces or blood.

Experiment IX. Effect upon aniline dyes.—Silks dyed with aniline colours, as supplied by the "Farbwerke vorm. Meister Lucius und Brüning, Höchst," as patterns (standard colours on silk, 1894, No. 360), were exposed for 24 hours to the action of formalin vapours produced by two Formogène Richard lamps. It was found that the dyes were not destroyed or even altered in the slightest degree. Weak solutions of the following stains—methylene blue, gentian violet, Victoria blue, dahlia, methyl violet, thionine, Hoffmann's blue, Ehrlich's hæmatoxylin, and hæmalum—were similarly exposed for 24 hours, with the result that hæmalum alone was bleached. Therefore the formalin gas evolved by this lamp was perfectly harmless to the dyes in general use. It may be remarked also that metal and polished wood were in no way affected.

These results show the limits of room disinfection by these formalin lamps and I shall reproduce them in the shape of final conclusions. In other experiments which need not be detailed here I was able to confirm the view expressed by others, that active formalin vapours act best in a warm atmosphere, for I found that when I kept the gas burning during the twenty-four hours there were generally less failures with the sterilisation of dust than when the experiment was carried out under ordinary conditions.

FINAL CONCLUSIONS.

So far as my experiments go, Formogène Richard lamps are much more certain in their action than Alformant lamps A and B. Of the latter, B appears to me to be valueless, except as a deodorizer and A is too uncertain.

1. With regard to the Formogène Richard lamp it is necessary, as numerous preliminary experiments have shown me, to use two lamps, even for so small a room as the one in which these experiments have been made.

2. Formalin does not penetrate deeply and, as admitted by all competent observers, cannot be used for the sterilisation of blankets, linen, &c., heaped one upon the other; it is merely a superficial disinfectant.

3. It must be pointed out that blood and fæcal stains are indelibly fixed in handkerchiefs and linen and such like material. Such articles must therefore be disinfected by means of boiling or steaming.

4. Metal, dyes, and most colours are not destroyed, although some aniline dyes may be slightly altered.

5. Dust and soil are not sterilised with certainty.

6. I agree, therefore, with F. Abba and Rondelli,[1] that formalin, if efficiently produced, is useful for the superficial disinfection of such substances as are injured by steam or liquid disinfectants or by irritant gaseous bodies such as chlorine.

When using the Formogène lamp for disinfection of a room strips of linen impregnated with staphylococcus aureus must be placed in the room as indicators; the disinfection is not complete unless these strips are sterile (Pfuhl's test).

A table has been prepared which allows of a ready comparison between the results obtained by the Alformant Lamp (A) and those obtained by the Formogène Lamp. It is evident from the table that results obtained with the latter are much more favourable than those obtained with the former. The experiments were conducted under identical conditions; the strips were exposed in the same places, they were prepared in the same manner, and subsequently tested by the same method. Recently Schlossmann has described a new process of disinfection by formalin vapours which was tested in the Institut für Infectionskrankheiten and was pronounced to be highly efficient. As yet I have found difficulty in procuring this apparatus and therefore propose to report upon the same later. Trillat's apparatus I do not intend to discuss, because it is but little known in this country. It also, as shown by others, is useful only for superficial disinfection, and in this respect, provided that active formo-chloral has been used, works as well as, and no better than, the Formogène Lamp.

OBSERVATIONS ON AN INFECTIOUS DISEASE IN LASCARS HAVING CLOSE RELATIONS WITH VARIOLA AND VARICELLA.

BY R. S. THOMSON, B.Sc., M.D., C.M. GLASG.,
VISITING PHYSICIAN, CITY OF GLASGOW SMALL-POX HOSPITAL, BELVIDERE, ETC.,
AND
JOHN BROWNLEE, M.A., M.D. GLASG., D.P.H. CAMB.,
LATE ACTING SUPERINTENDENT, CITY OF GLASGOW SMALL-POX HOSPITAL, BELVIDERE.

THE following observations made upon a number of lascars admitted to the City of Glasgow Small-pox Hospital, Belvidere, in the spring of 1898 are of considerable interest in so far that the clinical features of the disease from which these men were suffering suggested in certain cases variola and in others varicella, while in all some of the symptoms presented were alien to both. 16 cases of the disease were observed in various stages. Some came under observation as early as the second day of illness, while others were not admitted to the wards till the fifth or sixth day. In one case only was the whole course of the disease observed from its onset till its termination. The patients were lascar seamen from a steamship trading between Calcutta and Glasgow. On board this vessel 69 lascars were employed, who were accommodated in the forecastle and came little into contact with the European members

Digitized by Google

of the crew. So far as could be ascertained none of the lascars left the vessel during the voyage and the outbreak of the disease did not become manifest till after the arrival of the ship in Glasgow, when it was thoroughly overhauled and certain extensive alterations were carried out. During the progress of this work about 250 British workmen were employed and these, entering the forecastle freely and even cooking some of their food there, came into intimate contact with the lascars. It is important to note that the lascars and Europeans mixed together thus freely, even at a time when some of the former who were suffering from the disease were presumably in a highly infective condition. We should observe that, as far as could be ascertained, not one of the European artisans employed on board had been revaccinated. The cases were admitted to hospital between April 1st and May 7th and occurred in successive groups separated by periods which might be justly regarded as representing those of incubation. Owing to the fact that the earlier cases were certified as cases of small-pox the forecastle and other parts of the ship frequented by the lascars, as well as all clothing, were thoroughly cleaned and disinfected, consequently it seems legitimate to conclude that the infection in the later cases took place from man to man and was not the result of fomites. During the earlier part of the outbreak the precautions taken by the sanitary authorities were those which would have been carried out had the outbreak been one of small-pox, the disease from which the lascars, at least at the outset, were supposed to be suffering. With this diagnosis in view revaccination was offered to the British workmen but was refused absolutely by them all, though revaccination was carried out on all the crew. It thus appeared that the artisans were exposed to the infection without any recent protection against small-pox and that they came into personal contact with those of the lascars who were sickening from the disease or who were in its later stages. Contact with the latter class of cases certainly occurred, as some of those who were admitted to hospital were persons who had been going about freely for some days after the disease had declared itself and who were presumably, therefore, in a highly infective state.

History of the outbreak.—The steamship in question left Calcutta on Feb. 10th, 1898, Colombo on the 18th of the same month, Suez on March 1st, Port Said on the 2nd, Malta on the 6th, arrived at London on the 15th, and finally reached Glasgow on the 22nd. Small-pox was present in Calcutta, Port Said, and Suez while the ship was in these ports, and hence there was a possibility of infection from each of these sources, but, as already observed, the lascars were not permitted to land and could have been infected by small-pox directly only in Calcutta or indirectly at the other ports through the European members of the crew. This greatly reduced the chance of infection from small-pox and it must further be noted that, as will be seen later, the period of incubation of this disease, so far as it can be ascertained, excludes the likelihood of infection at intermediate ports, leaving Calcutta only as the centre from which the disease was carried. The first case of illness among the lascars was noted on board ship about March 10th. On April 2nd three lascars were admitted to the hospital presenting an eruption in various stages of desiccation. Judging from subsequent experience it is probable that these patients had already been ill for five or six days, their illness presumably commencing about March 27th. A single case had been admitted on April 1st, but this was of more recent origin than the others. A second group of 8 cases came under observation between April 13th and April 19th. The later members of this group were possibly infected by a member of the lascar crew who had been overlooked and who was not admitted to hospital till April 7th. A third group of 3 cases came under observation between May 3rd and May 7th. There were no deaths.

Features of the disease.—The eruption was the most outstanding feature of the disease. Speaking generally, it may be described as consisting of three stages—a papular, a vesicular, and a desiccative or crusting stage. While it is convenient for purposes of description to classify the phases of the eruption in this manner, it is important to note that the papular and vesicular forms were frequently seen together on adjacent parts of the body at the same time. In the cases which came early under observation the great bulk of the eruption was papular, but even on the first day of the eruption a few vesicles could in some of the cases be seen in various parts of the body, but notably on the trunk. Whether these vesicles were invariably preceded by a papular stage it is very difficult to say, owing to the limited number of cases observed, but if this were so then in some instances at all events the papular stage must have been very evanescent. The papules themselves were mostly of considerable size, hard, somewhat shotty, and acuminate. No distinction of colour could be made out between them and the surrounding skin in their earlier stage of development; in fact, at this period they were more palpable than visible. Later, however, they became of a deep-red or dusky colour. While in each case a considerable number of the papules vesiculated, yet in most of the patients the bulk of, and in two cases practically all the papules showed no tendency towards vesicular change. When thus arrested in development the papules gradually disappeared as convalescence advanced without crusting, evidently undergoing a process of direct absorption. In the later stage of papulation these eruptive elements which were about to vesiculate became surrounded by a well-marked red areola and this process was also observed in the case of a small number of papules which did not undergo further change before all trace of them was lost. The vesicles in most instances, and possibly in all, developed from papules, the process of vesiculation beginning at the apex. In some elements the change seemed to be early arrested, the vesicle becoming crusted while still very small and before the base of the papule had undergone any appreciable change. When vesiculation had advanced to its fullest extent the eruptive elements were somewhat irregular in outline though occasionally almost circular. They measured from $\frac{1}{8}$ in. to $\frac{1}{4}$ in. in diameter, but a few were larger than this. The vesicles contained an almost clear fluid, but they did not present the brilliant glassy appearance so characteristic of the early varicellar vesicle, more closely resembling small bullæ such as might have been produced by drops of scalding water sprinkled over the skin. These vesicles on palpation presented a very marked sense of resistance or "body" and in this respect reminded one very forcibly of small-pox vesicles, the fragile character of the varicella vesicle being almost entirely absent. The vesicles were unilocular, but the interior cavity in most cases examined was partially divided by fine trabeculæ. Umbilication was absent altogether from the fully developed vesicle, but as desiccation commenced in the oldest parts of the element—i.e., those nearest the centre—those parts became depressed, giving rise to a pseudo-umbilication. Each vesicle was surrounded by a dark-red areola, often of considerable width and presenting a very decided sense of infiltration to the touch; this areola persisted well into the stage of desiccation. The fluid within the vesicle, while originally clear and serous-looking, became cloudy later and distinctly sero-purulent, but in no instance was a true pustule formed. A microscopic examination of the fluid in the earlier stage revealed no detectable micro-organism, even the staphylococcus being absent. The course of the vesicle was practically the same in every instance, with the exception of a few which were ruptured by direct violence. The vesicles gradually developed, as above described, attaining their fullest growth in from twenty-eight to forty-eight hours from their first appearance, at which time they were extremely tense and unyielding. Thereafter the tenseness slowly subsided, evidently as the result of absorption, the vesicle becoming softer and more flaccid, as so frequently occurs in small-pox. The whole duration of the vesicular stage varied from thirty-six to seventy-two hours. In the case of those vesicles in which rupture occurred the base was found dense and infiltrated. The process of crusting, as already remarked, began in the central part of the vesicle and gradually extended outwards. This process occupied a considerable time and in most cases the periphery of the vesicle remained soft and moist for several days, while the centre was covered with a brownish crust. The scabs had the appearance of those seen in some cases of modified small-pox, being of a reddish brown colour and of some little thickness; they resembled neither the thin superficial crust so familiar in varicella nor the coarse crusts so characteristic of unmodified small-pox. These were not readily separated even after complete desiccation had taken place and when forcibly removed they left behind a bleeding surface. Later, when complete cicatrisation of the subjacent tissue had taken place, removal of the crusts revealed a moderately deep and well-marked pit

Digitized by Google

penetrating through the Malpighian layer of the skin, as was evident from the complete destruction of the pigmented tissue, the cicatrices having a white colour slightly tinged with pink. These pits were foveated, persistent, and well marked when the patients left the hospital at the end of three weeks.

Period and distribution of the eruption.—In one case[1] in which the disease developed after admission to hospital the eruption was present on the first day, and in a second case, in which the patient was admitted on the first day of illness, the eruption was also found. It is difficult to say exactly at what period of illness the eruption first appeared among those who were not observed from the onset, but there seems little doubt that in a certain proportion at any rate of these cases the eruption appeared on the first day. On the second day of illness the eruption was well marked in all the cases which came under observation within that period, by which time, at least in the majority of cases, it seemed to have attained its maximum so far as the number of elements on the trunk was concerned; papules appeared on the lower extremities rather later than on the trunk and other parts of the body. It is exceedingly difficult to say whether the eruption invariably appeared in what might be regarded as one crop or whether in some instances more than one crop appeared; but it is certain that in a great majority of the cases, and more especially in those in which the bulk of the eruption remained papular throughout, the tendency was for one crop and one only to develop. This was true of 9 of the 16 cases which came early under observation, while in 2 cases it was thought that a second crop might have developed, but the evidence of this was not regarded as conclusive. In 5 cases the illness was so far advanced when the patients were admitted to hospital that this point could not be decided. The eruption appeared first upon the face and trunk but did not seem to have any special affinity for the former. It was usually most abundant on the back. Elements of eruption likewise appeared on the scalp, chest, and arms, but were especially sparse over the abdomen. In none of the cases was the eruption found on the palms and soles. On the legs the elements were more sparsely scattered and appeared later than elsewhere. In the throat in 7 out of 13 of the cases which came under observation at a sufficiently early period of the illness a variable amount of eruption was seen on the fauces and palate. The remaining 3 cases were admitted when any faucial eruption which might have been present earlier in the case must have completely disappeared.

Temperature.—Some of the cases were admitted to hospital so late that the febrile period had entirely passed when they first came under observation. In about half the cases, however, where admission followed the onset almost immediately it was possible to observe the whole of the pyrexial movement. In every case observed at this early time there was a decided elevation of temperature, which, however, varied in amount in different cases and seemed to have little relation to the amount of the eruption. In different individuals the highest febrile point attained varied from 100°F. to 104°, and the duration of the febrile period from three to six days. The termination of the fever was marked by a short lysis and in one case by a very decided critical fall. The eruption appeared within a few hours of the onset of the febrile symptoms and there was nothing in the course of the temperature at all suggestive of that defervescence which is so characteristic a feature of many cases of unmodified small-pox with the first appearance of the eruption. The fever had more or less of a remittent character, the difference between morning and evening temperature sometimes amounting to as much as 2° or 3°. In some of the cases the highest temperature registered was 101°; in others, however, the febrile disturbance was very marked, the evening temperature in 2 cases reaching 104° and varying between that and 103° for five or six days. The actual rise of temperature at the period of onset was observed in one case only and in this the temperature attained its maximum of 104° in the course of a few hours.

General course of the attack.—The onset of the disease was sudden and associated with general symptoms of fever, as headache, sickness and vomiting, thirst, loss of appetite, malaise, muscular weakness, and febrile pain. Headache in one or two cases was very severe and in some backache was a clamant symptom. Sleeplessness was marked in several of the cases but delirium was not observed. The eyes were suffused in several instances, but this condition passed off with the fever. The tongue was covered with a whitish or slightly yellowish fur and the bowels were constipated. The urine presented febrile characters, but though two samples from each case were examined daily albumin was found in only one case early in the febrile period and had completely disappeared by the beginning of the fifth day of illness. There was nothing abnormal found in the liver or spleen, the lungs or heart, on careful physical examination. The pulse was moderately rapid, but not more so than might have been expected to be associated with the febrile state in each case. In addition to the fauces presenting eruptive elements in some cases, the mucous membrane of the fauces, pharynx, and palate was found congested in nearly every case which came under observation early in the attack. As already stated, the disease ran a febrile course of from four to seven days, the general symptoms disappearing with the fall in the temperature. No complications were observed in any instance.

Relation to vaccination and antecedent small-pox.—3 of the 16 cases presented evidence of antecedent small-pox—namely, deep pitting, especially on the face. Of these 1 had suffered from an attack of small-pox evidently of a very severe type twenty-six years before he came under our observation, while the other 2 had suffered from milder attacks at periods varying from two to three years before their admission to the wards. With regard to the first patient, vaccination had apparently been successfully performed at some period subsequently to the small-pox attack. A second patient presented two well-marked vaccinia cicatrices, but it was impossible to discover whether vaccination had been performed before or after his attack of small-pox. No evidence of vaccination could be found in the third case. The remaining 13 had all been successfully vaccinated in early life and showed proof of this by the presence of well-marked and in most cases good vaccinia scars. 5 of the patients were revaccinated during the earlier period of the disease or while crusts were still adherent. This was done rather as a test than as a prophylactic measure. In 4 cases vaccination proved completely successful and in 1 case it failed. This case was one of those already referred to as having suffered from a comparatively recent attack of small-pox. The other 11 cases were successfully revaccinated on board the ship from two to four weeks before the onset of the disease we are now considering, and in all the revaccination had completed a typical course some little time before the first appearance of symptoms.

Specific characters of the disease.—Having described in detail the eruption and general symptoms of the disease the nature of the diagnosis now falls to be decided. As stated in the early part of this paper, the disease presented some characters suggestive of small-pox and others suggestive of chicken-pox, while certain points, notably in the character and course of the eruption, presented features differing from both of these. That the disease was a specific one is evident from the manner in which the cases occurred in successive groups separated by periods varying from ten to fifteen days. The first of these periods between the outbreaks extended to fifteen days, the second to ten days, and the third to thirteen days. The last two intervals represent minimum periods. If, as we are quite entitled to do, we exclude possible infection from clothing there seems little reason to doubt that these must be regarded as representing a period of incubation which, while it would be impossible to fix its actual duration from the data at our command, might be approximately represented by from ten to fifteen days—a period of incubation with which we are familiar as occurring very frequently in other forms of specific infectious disease. The gradual development of the eruptive elements on the skin, coupled with the definite course presented by the disease and the similarity of the eruption among different cases, point to the same conclusion. Another circumstance bearing in the same direction is to be found in the gradual increase in the number of cases in the second and third groups; the first case was followed by a group of 5, and that again by a group of 8, while the last was followed by a group of 3, the falling off being probably due partly to the precautions taken and partly to a lack of susceptible individuals.

On admission of the cases to the hospital the question

[1] This patient was admitted to hospital on account of the presence of two small scars over the ensiform cartilage which it was supposed might have been due to a recent attack of the malady.

Digitized by Google

which presented itself for decision was whether the patients were suffering from small-pox. After an examination of the cases, a careful consideration of the history, and a study of the course of the attack, it was decided that small-pox (as an alternative diagnosis) must be entirely excluded on the following grounds:—1. The coincidence of the rash with the onset of the general symptoms, the temperature rising and advancing to some extent at least with the development of the eruption. 2. The entire absence of anything like a secondary fever such as we find even in some cases of modified small-pox. 3. The absence of any special predilection of the eruption for the face and scalp, the bulk of the rash appearing mostly on the back, chest, and arms. 4. The entire absence of eruption from the palms and soles in every case observed. 5. The rapid transformation of the papules in certain cases into vesicles, the latter being occasionally present even on the first day of illness. 6. True pustules were not seen in any instance. In addition to these clinical reasons for putting small-pox entirely out of consideration a certain amount of weight was given in the decision to the fact that three of the patients had already passed through an attack of severe small-pox, 2 of them comparatively recently. The small-pox in at least 2 of the cases was unmodified. 4 of the patients were revaccinated successfully during the crusting stage, while the others had been revaccinated with success from two to four weeks before the first appearance of symptoms. It may be supposed that comparatively little value should be attached to this point, but the successful vaccination of small-pox convalescents as well as the occurrence of small-pox so soon after successful revaccination is entirely contrary to the experience of small-pox in Glasgow. An examination into this question among the cases treated in the hospital during the last five years shows that 52 small-pox patients were vaccinated at various periods during the stage of eruption and convalescence, some twice or even thrice, but in no single instance was any reaction manifested, except in some cases a slight redness of the skin such as might occur in the neighbourhood of any superficial wound. As already stated, these patients came into intimate contact with 51 other lascars on board ship, of whom 2 were unvaccinated, and 250 British workmen of varying ages, of whom none had been revaccinated, and yet not one of these contracted the disease. This exemption of over 300 intimately associated persons, many of whom from absence of revaccination and a few from absence of primary vaccination were probably susceptible to the small-pox poison, is likewise entirely opposed to our experience of the behaviour of small-pox under similar conditions. The complete exemption of Europeans both on board ship and in hospital from this disease is noteworthy.

Varicella is the only other specific disease suggested by the clinical features of the cases under consideration. In some respects the resemblance of the disease to chicken-pox was very striking, notably the coincidence of the onset with the first appearance of the eruption as well as the general character of the fully developed rash and the rapid evolution of certain of its elements. On the other hand, the bulk of the signs and symptoms showed little or no resemblance to those which we are accustomed to regard as most characteristic of chicken-pox. The papules which constituted the first stage of the eruption were quite unlike those seen in varicella. In the disease which we are discussing these were large, hard, dense, and frequently cone-shaped, the apex being more or less pointed. At first they were colourless and not readily detected by the eye, though they could be felt in the skin as small, hard, and somewhat shotty masses; later, as already explained, they assumed a dusky-red colour. In all these points they differed from the papules of true varicella, which are small, soft, and somewhat velvety to the touch, flat, and of a bright-red colour, and which present an entire absence of that shotty feeling which was so notable a feature of the former eruption. Further, we find that in some of the cases the great bulk of the papular elements, and in one case the whole of them, showed no tendency to vesiculation, but gradually disappeared by absorption of their solid constituents in a manner similar to that which is occasionally seen in modified small-pox.

The majority of the elements which underwent progressive growth did not vesiculate till the second or even the third day from the first appearance of the papules. The frequency of the eruption in the throat with the very marked catarrhal condition of the fauces and the invariable absence of the eruption from the palms and soles are also, in view of the age of the patients, unusual features of varicella. In the latter eruptive stage the very wide areola, the slow process of desiccation, and the deep pitting without any evidence of secondary infection (as gauged by the absence of pyogenic organisms from the vesicles) cannot be explained on the supposition that the disease was varicella. With regard to the symptoms the high temperature observed in most of the cases, with the severe pain in the back and vomiting, while not to be insisted on are yet in favour of the view that the disease is not varicella; besides, the fact that it occurred in so many adults points in the same direction. The following report of one of the cases furnishes a clear clinical picture of the condition under consideration.

The patient, a seaman, aged twenty-five years, who had been vaccinated in youth was revaccinated successfully on April 2nd. He was admitted to hospital on April 16th, having fallen ill the day before with symptoms of fever, including malaise, headache, debility, &c. There was no pain in the back and no vomiting. The eruption was seen for the first time on the same day. The temperature on admission was 103° F. When seen in the hospital there was a marked eruption of papules on the face, presenting the usual variolous character and distribution, though less marked along the roots of the hair than is often seen in small-pox. There were a few papules on the scalp. On the trunk, back and front, there was a similar papular eruption, mixed, however, with varicella-like vesicles of about the size of a split pea, a few of which had begun to show commencing crusting in the centre; in addition a few of the elements contained opalescent fluid. The eruption was moderately abundant on the trunk but very sparse on the limbs, the more advanced elements being surrounded by a dusky-red areola. There was no eruption on either the palms of the hands or the soles of the feet. The fauces and the soft and hard palates were markedly congested and they presented an abundant eruption of vesicles. There was pain on swallowing. By April 18th the elements on the face were vesiculating, while the vesicles on the trunk were advancing in the process of crusting, those less advanced being sero-purulent, hard, tense, and indistinguishable from those of varioloid. Umbilication was present only in the vesicles in which crusting had begun. On the morning of the 19th the temperature, which had been 104° on the preceding night, was 101°. The eruption on the face was crusting in parts, the most advanced vesicles showing a small reddish crust in the centre, while the less advanced were still sero-purulent. Some of the original papules on the trunk continued unchanged. The malaise was passing off. On the 20th the temperature was normal. Desiccation of the vesicles had continued but was not yet complete. Some of the original papules remained unchanged, there being no indication of vesiculation, and these were becoming gradually absorbed. On May 2nd the patient was dismissed. The general health was good and the only remains of the eruption were to be found in the presence of a number of moderately deep cicatrices of a pale reddish colour on the face and trunk.

An examination of the literature dealing with variola, varioloid, and varicella fails to furnish any allusion to a disease similar to that which we have just described, except in a paper read before the Epidemiological Society of London by Dr. Izett Anderson in 1866 and published in the Transactions of that society in 1867.[2] Dr. Anderson's description applies to an outbreak in Kingston, Jamaica, of a disease which was evidently neither variola nor varicella and which presented features closely resembling the disease from which the above patients suffered. The following points of resemblance in the description referred to are very striking. 1. The period of incubation amounted to about fourteen days. 2. The febrile period was short, up to five or six days being its usual duration, while the temperature was of a decidedly remittent type. 3. There was an absence of secondary fever. 4. There was a constant catarrh of the throat with the presence of an eruption on the soft parts in many cases. 5. The eruption presented a papular stage, a vesicular stage, and in some cases a pustular stage. (*a*) The papular stage was of considerable duration, vesiculation occurring in from twenty-four to forty-eight hours from the first appearance of the rash, which showed itself first on the face and extended to other parts, though in some cases it was absent from the

[2] On Epidemic Varioloid Varicella in Jamaica: Transactions of the Epidemiological Society of London, vol. ii., p. 414.

Digitized by Google

face throughout; (*b*) the vesicles were mostly hemispherical, tense and ranging in size up to that of a split pea, showing in some cases slight umbilication, in some cases the fully developed vesicle resembling that of variola, in others that of varicella; (*c*) a pustular stage occurred only at times and does not seem to have been constant. This was followed by the formation of crusts, and these on separation left cicatrices which were still present when the cases were examined some months later. 6. The various stages of the eruption were observed at the same time closely associated on the same parts of the body. 7. The disease occurred equally in vaccinated and unvaccinated subjects, as well as in those who were deeply pitted by antecedent small-pox. Dr. Anderson's description contains symptoms not observed in the cases which came under observation at the Belvidere Hospital. In his patients (1) the date of appearance of the eruption as stated in his paper is a little indefinite, but it seems in some instances to have appeared in the course of the third day; (2) no mention is made of the persistence of papules and the whole of the eruption is said to have vesiculated; and (3) a true pustular stage seems to have been observed (the nearest approach to this among the cases here dealt with was a sero-purulent condition of the contents of some of the eruptive elements). From Dr. Anderson's statement that the pustules ruptured and in some cases gave rise to superficial sores it is quite possible that the purulent condition may have resulted from secondary infection by pyogenic organisms; but, on the other hand, it must be remembered that as Dr. Anderson observed 115 cases it is likely he would have had the opportunity of noting greater variation in the type of the rash than ourselves. A due comparison of the clinical features observed in these cases by us with those set forth in Dr. Anderson's paper warrants the belief that the disease is neither variola nor varicella, but is probably a third disease of a specific character presenting resemblances to both, while at the same time it possesses certain features which entitle it to be placed by itself as a specific entity and bearing the same relation to both the diseases mentioned as exists between the more familiar forms of small-pox and chicken-pox. It is, of course, possible that the condition may be merely a modification of varicella the result of racial difference, and Dr. Anderson gives no clue in his paper as to whether the disease limited its attacks to the dark race or involved the white population also, but as he refers to cases occurring in his private practice similar to those which he observed in the prison and penitentiary it is quite likely that whites as well as negroes were victims of the disease. If this inference be correct then the argument that the disease is merely a modified varicella due to racial conditions must fall to the ground, although in connexion with this point it must not be overlooked that climatic rather than racial conditions might result in modifying varicella at least to some extent. Our opinion, based upon observation of a large number of cases both of variola and varicella, is that almost certainly the disease should be regarded as a specific entity. This conclusion, if correct, would explain certain peculiarities from time to time reported as occurring among small-pox patients in the East — e.g., susceptibility to vaccinia after passing through what is supposed to have been an attack of small-pox as well as other somewhat anomalous conditions with which we in this country are unfamiliar.

Glasgow.

THE STERILISATION OF CATGUT BY DRY HEAT.

BY J. H. DAUBER, M.A., M.B., B.CH. OXON., M.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR WOMEN, SOHO.

IN the issue of THE LANCET of Oct. 1st Mr. Mayo Robson drew the attention of the profession to his method of sterilising catgut by boiling it in di-methyl-benzene and thence transferring it before use either to a 5 per cent. solution of carbolic acid or to methylated spirit. As the details are not known to everyone I should like to mention another method of sterilisation—i.e., that by dry heat, which also has the merits of simplicity and efficacy. It is much in vogue on the continent and also I believe in America. (Boxes and sealed tubes of dry sterilised catgut can be purchased at many instrument makers in this country, but personally I have a preference for using, in a matter of such importance, an article the preparation of which need not be taken on trust.)

The following is the method of sterilising catgut adopted by Professor Tscherning of Copenhagen, who recently very kindly showed me the details observed by himself in its preparation at the Kommune Hospital in that city. The ordinary commercial catgut as it comes from the manufacturer is placed on trays in the steriliser between sheets of cellulose paper. It is then heated for six hours consecutively, for the first hour at a temperature of 60° C., for the second and third hours at 100° C., and for the fourth, fifth, and sixth at 140° C. It is then removed, wrapped up and closely sealed in an envelope of cellulose paper which is again placed in another envelope of slightly larger size and similarly closed. The catgut now encased within two firmly sealed envelopes is a second time placed in the steriliser and subjected for another two hours to a temperature of 140° C. The envelopes are placed in racks in the steriliser and contain various sizes of catgut labelled on the outside, some of a size for ligaturing the pedicle in ovariotomy, others for fine buried sutures or other purposes where absorption is desired within a short period. These envelopes can be taken from the steriliser and placed in the pocket or bag of the operator and need not be opened until the time of operation. Thus they are very handy and portable. It is to be remembered that catgut ligatures prepared by any of the wet methods become, if kept in spirit for any length of time, hard and need more time for absorption. If, on the other hand, they are kept in an antiseptic aqueous solution they tend to become soft and lax, whereas if kept in any preparation of glycerine they are somewhat difficult to manipulate owing to their extreme slipperiness. The dry catgut is without these disadvantages. The method of raising the temperature by slow degrees prevents the catgut becoming brittle—the grease and oil in the gut being driven off gradually at the lower temperatures.

Charles-street, W.

REMOVAL OF A CALCULUS FROM THE COMMON BILE DUCT 2 IN. LONG AND 3½ IN. IN CIRCUMFERENCE WITHOUT SUTURING THE DUCT.

BY H. J. THORNTON, L.R.C.P. LOND., M.R.C.S. ENG.,
FORMERLY HOUSE SURGEON TO THE MIDDLESEX HOSPITAL; SURGEON TO THE PASSMORE EDWARDS COTTAGE HOSPITAL, ACTON.

THE patient was a man, aged fifty-eight years, a gold prospector by trade, and was one of the early pioneers of the Western Australian goldfields. He was a man of splendid build, spare in frame, strong, and active. His life had been full of hardship from rough food, bad water, &c., on his travels. Except accidents he never suffered from any serious illness until four years ago, when being in Adelaide he began to get attacks of pain, vomiting, and slight jaundice. These occurred often at intervals of only a few days, sometimes weeks. Sometimes after attacks he passed small gallstones by the bowel. The pain was so severe that he had to have hypodermic injections of morphia, and it was so continuous about two years ago that he became reduced to an extreme degree of emaciation. After undergoing rest and medicinal treatment at a hospital in Melbourne, with careful diet, he improved a good deal, but the attacks still recurred at longer intervals, and just previously to coming to England twelve months ago they became of daily occurrence. He stated that he could not prevail upon the Australian surgeons to operate, so he determined to come home. On examination there was distinct tenderness and a sense of obscure fulness over the region of the gall-bladder, but deeper than that organ. Although the patient was very thin, no enlargement of the liver or gall-bladder could be detected on palpation or percussion. The patient was jaundiced, having recovered from a severe attack of biliary colic only a few days previously. As the history seemed so plain it was determined to open the gall-bladder and to explore the cystic and common bile ducts.

Digitized by Google

Mr. Bland Sutton, assisted by myself, chloroform being administered by Mr. Owen Coker, made an incision from the margin of the ribs on the right side down in a line with the outer border of the rectus muscle, about 3 in. in length, and the peritoneum was incised. There was no enlargement of the gall-bladder but a small stone could be felt in it. The gall-bladder was opened and this was removed. It was quite loose in the viscus. Behind the gall-bladder, underneath the liver could be felt indistinctly a large resisting body in the situation of the common bile duct. The abdominal wound was enlarged, the liver was pulled up as high as possible, and the pylorus was pulled aside. After cautiously working down with the finger Mr. Bland Sutton came on the greatly distended common bile duct, and in this, just past the opening of the cystic duct, was felt a large stone. Strong efforts were made to push it back into the gall-bladder or onwards into the bowel, but, owing to its size, without avail. An incision about 1½ in. long was made in the long diameter of the duct and the stone was easily expressed. It was composed of cholesterin, was 2 in. long and 3½ in round, was quite smooth, ovoid in form, and weighed 7 drachms. There was but slight bleeding. The incision in the duct was not sutured. A large indiarubber drainage-tube was put in down to the bottom of the abdominal wound, the gall-bladder was closed and stitched to the parietes, and the abdominal walls were closed by three layers of sutures—fine silk for the peritoneum, silkworm gut for the muscles and fascia, and silk for the skin and subcutaneous tissues. It was dressed with the usual antiseptic dressing. After the operation the patient suffered a good deal of pain, which was relieved by small hypodermic injections of morphia for the first twenty-four hours. The temperature never rose above 100° F. and the pulse kept good. There was for the first three days a profuse discharge of bile, at least 2 or 3 pints daily, requiring frequent dressing of the wound. The tube was gradually shortened and it was removed altogether in about seven days. There was no discharge of bile after the third day. The abdominal wound closed by first intention and the patient made an uninterrupted recovery, with the exception that several of the buried silkworm gut sutures caused small abscesses and were gradually in the course of some months brought to the surface and removed quite undissolved. Since the operation he has never had another attack of biliary colic. He has gained 3½ st. in weight and can eat any ordinary food with impunity. The scar is firm and strong and there is no ventral hernia.

Acton, W.

A CASE OF PYÆMIA TREATED WITH INJECTIONS OF ANTI-STREPTOCOCCIC SERUM.

BY HERBERT M. RAMSAY, F.R.C.S. EDIN.

A GIRL, aged fourteen years, developed measles on Feb. 27th, 1898. She went on well, it appeared, until March 3rd, when, at about 4 A.M., she complained of pain in the right ear. The pain continued to get worse, the child throwing herself about in bed all through the day and night of the 3rd. On the morning of the 4th the pain got better and the nurse noticed some discharge from the ear. In the evening the temperature was 104° F. and the patient complained of pain behind the ear. I saw her for the first time on the evening of the 5th, when her temperature was 105°. She had had a "shivering fit." Her pulse was 120, the respirations were 24, and she was very restless. There was some pain behind the right ear, but this was not increased by pressure and there was no redness or swelling there. On examining the ear I found the meatus filled with inspissated pus and débris and on clearing this out the membrane was seen to be white and sodden and there was a perforation situated at the anterior and inferior part of the membrane. After this her temperature fell to 103° and she had some sleep. The ear was ordered to be kept syringed out with a perchloride of mercury lotion (1 in 4000) and a 2-gr. pill of quinine was directed to be given every six hours. When I saw her again on the evening of the 6th the patient's temperature had gone up to 104° again, her pulse was 120, and the respirations were 26. I found that the meatus was again blocked with pus and after cleaning this out her temperature fell during the night to 99° and there was a profuse discharge from the ear. In spite of her ear being kept well syringed her temperature rose on the evening of the 7th to 106°. Her pulse was then 130, the respirations were 30, and some dulness was detected at the base of both lungs. She still complained of pain behind the ear and the tip of the mastoid was very tender on pressure. On the 8th her temperature kept at about 103° and there was free discharge from the ear. She was restless and sick several times after food, but there was no delirium. The quinine was increased to 2 grs. every four hours and she was given a drachm of brandy with each quinine pill. Mr. Bowlby saw the patient with me on the evening of the 8th, and we decided that there was no immediate indication for opening the mastoid cells. Her temperature was then 105·4°. She complained of pain at the tip of the mastoid, and this spot was tender on pressure, but there was no pain or tenderness over the mastoid cells and no headache. She was restless but she had no cerebral symptoms and there was no tenderness over the course of the jugular vein. She had been sick several times after her food and she had had a slight rigor. She slept fairly well and was better on the 9th, but there were patches of dulness all over both lungs, with fine crepitation and tubular breathing. She had a slight cough but very little expectoration. Her temperature in the evening was 104·6°, her pulse was 104, and the respirations were 32. On the morning of the 10th her temperature was 99° but it rose again in the afternoon to 104·4°, when Mr. Bowlby again saw her with me. The patient was now very ill and it was decided to open the mastoid cells, which was done at 4.30 P.M., when Mr. Willett administered the chloroform. Mr. Bowlby opened the mastoid cells and found nothing there except some muco-purulent secretion, but not sufficient of this to account for the high temperature, so no attempt was made to open up the tympanum. The skull was then opened but the dura mater did not bulge and the lateral sinus was evidently not occluded and the wound was therefore closed. The patient took chloroform well and she went to sleep after ⅓ gr. of morphia had been injected subcutaneously. Her temperature rose to 105° in the evening, but on the morning of the 11th it fell to 99·4° and she seemed to be much better. In the afternoon, however, she had a slight rigor and her temperature rose once more to 105°. The respirations were 38. On the 12th she was troubled a good deal by cough and had some purulent expectoration. Her temperature in the morning was 96·4° and in the evening it was 104·4°. She had well-marked pneumonia in patches over both lungs. Her condition on the 13th and 14th was much the same. The patient was troubled by cough and she was restless and took her nourishment badly. On the night of the 14th she slept very little and complained of pain in her right wrist and hand. The temperature on the morning of the 15th was 101·4°. The right wrist being swollen and very painful it was dressed with belladonna and glycerine and put up on a light cardboard splint. The wound behind the ear was almost healed. She had a rigor in the afternoon and her temperature went up to 104°. On the 16th and 17th the patient was very ill. She had frequent rigors and her temperature ranged from 96° to 105°. She was very sick and restless. On the 18th the morning temperature was 96°, the pulse was 120 and very weak and the respirations were 32. She was constantly sick and took no notice of anything.

Dr. Herringham saw the patient with me at 6 P.M. on the 18th. Her temperature was then 104° and though the lungs were clearing up she still seemed very ill. It was decided to try injection of anti-streptococcic serum and Dr. Herringham accordingly injected 5 c.c. into the loin. For a short time she complained of pain at the site of the injection, but this soon passed off and she slept well and more naturally. The blood was examined and was found to contain numerous streptococci and a few staphylococci. There were streptococci in the sputum but no organisms were found in the discharges from the ear. On the 19th the patient had three injections of 10 c.c. each of serum at 8.30 A.M., 1 P.M., and 6.30 P.M. She seemed to have improved and she took her nourishment better. The urine was examined; it contained no albumin. On the 20th and 21st she had three injections each day, at 8.30 A.M. and 1.30 and 6.30 P.M. She was now decidedly better, but though she had no rigors her temperature remained high in the evening, though it was lower than it had been. The lungs were clearing up well

Digitized by Google

and she slept better. She was not sick and she took her nourishment more freely. There was no trace of albumin in the urine. On the 22nd her temperature in the morning was 98·6° and in the evening 102·5°. The pulse was 100 and the respirations were 26. As she was so much better and as, being a very nervous child, the thought of the injections distressed her so much, it was decided to discontinue them. The specific gravity of the urine was 1020 and there was a trace of albumin. On the 23rd she was much brighter and better and she took her nourishment well, though her temperature in the morning was 95° and in the evening 101·8°. The wrist was much better and she was able to leave off the splint. On the 24th the patient was not so well and her temperature was 102·4° in the evening. The urine contained no trace of albumin. She was given an injection of 10 c.c. of serum at 6.30 P.M. On the 25th she had three injections of 10 c.c. each and she again seemed better. Her temperature was still very low in the mornings and high in the evenings (104°), but her general condition was much improved. She complained of pain in the left buttock, where there was some fulness but no definite lesion could be made out. Belladonna and glycerine and hot fomentations were applied. On the 26th, 27th, and 28th she had one injection each day of 10 c.c. and she seemed to be steadily improving, though her temperature ranged from 104° to 95°. On the 29th she was not so well, her temperature was 102·4°, and two injections each of 10 c.c. were given at 8.30 A.M. and 6.30 P.M. On the 30th she was better, but she still complained of pain in the left buttock. She was given an injection of 10 c.c. at 8.30 A.M. and this was the last administered as the blood on examination showed no micrococci. Her temperature still varied from 95° to 104° but she ate and slept well. The chest was quite clear and the pulse was good and steady. On April 3rd and 4th she complained a good deal of pain in the left buttock and was quite unable to lie on that side. There was fulness, and as the skin was so tender that it was quite impossible to examine the place it was decided to put her under an anæsthetic for that purpose and this was done on the 7th. Fluctuation being detected Mr. Bowlby cut down and opened a large abscess situated beneath the glutei and evacuated about 10 oz. of pus. A counter opening was made and a large drainage-tube put in. Her temperature rose to 105° in the evening but she slept fairly well. On the 8th the patient was very sick all day and also on the 9th, on the evening of which day her temperature rose to 105·6°, her pulse was small (130) and running, and her respiration was shallow. She was very restless and delirious. The abscess was dressed but there was apparently no retention of pus and nothing to account for her condition. Morphia (¼ gr.) was administered subcutaneously, and after this she became quiet and slept for the greater part of the night. On the 10th she was much better, the sickness being less. There was little discharge and the wounds looked healthy. The temperature in the evening was 103·8 and she slept well. On the 11th her temperature did not rise above 100° and she was much better, but she had œdema of the right eyelid and the right side of her forehead. She took her nourishment well and with an appetite. From this time the patient continued to improve; the œdema of the eyelid disappeared and she was well enough to go to the country on April 23rd with the wounds almost healed. The drainage-tube was taken out on April 14th as there was no discharge. The patient was last seen on June 5th, when she had quite regained her strength and the hearing of the left ear was much improved. The perforation was healing, the site of the abscess in the buttock was quite sound, and the wrist was quite well.

The interest in this case lies in the great improvement manifested in the patient's condition after the serum treatment was commenced. The temperature did not fall though the average altogether was lower than before the injection but the continued high temperature was accounted for by the presence of the abscess in the buttock. When this was evacuated the temperature almost immediately fell to normal. In spite of the temperature being high the patient's general condition improved markedly. From the time the injections were commenced she slept better, took her nourishment better, and was altogether more natural. The wrist cleared up, her pulse improved, and she was brighter and better, whereas before she seemed in an almost hopeless state. This improvement was, I think, shown to be due to the anti-streptococcic serum treatment, as when for two days the injections were discontinued (from 8.30 A.M. on March 22nd till 6.30 P.M. on March 24th) she was manifestly not so well, and she improved again with the recommencement of the injections. Another point of interest is the complete disappearance of the organisms from the blood within twelve days of the commencement of the treatment. It is also interesting to note that streptococci were demonstrated in the blood and anti-streptococcic serum was used, as I think some cases of failure when anti-streptococcic serum has been tried may have been due to the organisms not having been streptococci. Altogether 205 c.c. of serum were injected by Dr. Herringham, to whom and to Mr. Bowlby my best thanks are due.

Hertford-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SUDDEN AND COMPLETE INVERSION OF THE UTERUS AND CERVIX AFTER THE MENOPAUSE; VERY SMALL FIBROID NODULE IN THE FUNDUS; GANGRENE; OPERATION; RECOVERY.

BY JAMES OLIVER, M.D., F.R.S. EDIN., F.L.S.,
PHYSICIAN TO THE HOSPITAL FOR WOMEN, SOHO-SQUARE.

THE patient was a widow, aged fifty-eight years, who had had six children and three miscarriages. The last child was born twenty years ago and the miscarriages occurred prior to that time. The menstrual discharge, which had always been rather profuse, ceased twelve months ago. During the last three months the patient had observed a slight and constant hæmorrhagic discharge from the vagina and had experienced occasionally "a feeling as though something were coming down in the front passage." Fourteen days ago there suddenly protruded from the external genitals a lump. The presence of this lump had been associated more with a feeling of discomfort than of pain and with the support afforded by a diaper the patient had performed her household duties as usual. Since the lump appeared the discharge had greatly increased and had become purulent and during the last four days it had been extremely offensive. There had been no bladder symptoms, neither had there been any disturbance of the rectum. There protruded from the external genitals a very sloughy mass which emitted an offensive odour and was composed of three lobes. The lower lobe, which was of the size of a walnut, was solid, the middle one, which measured roughly 3 in. vertically, had a somewhat cystic feel, whilst the upper one, which measured vertically about 2 in., had a membranous feel. Immediately above the upper limit of the mass the vaginal mucous membrane displayed anteriorly a dusky red line of demarcation, which extended a little way laterally but was absent altogether posteriorly. In the right lower half of the middle lobe, about an inch above the base of the lower lobe and slightly anteriorly, a small depression was discovered, into which a probe was passed for nearly an inch. As, however, it caused free hæmorrhage no attempt was made to pass it further, but it was evident that this was the uterine opening of the right Fallopian tube. The mere manipulation of the tumour caused free oozing of blood from the depression between the middle and upper lobes. Posteriorly this depression, which marked the level of the internal os uteri, was almost obliterated. The bladder sound passed straight up towards the pelvis and could not be made to descend towards the vaginal mass; the bladder retained, therefore, its normal position. The body temperature was 101° F. and the pulse numbered 90 per minute, but the patient otherwise appeared to be in good health.

The tumour and vagina were thoroughly washed with suds made from sapo mollis and afterwards douched well with carbolic lotion. The mucous membrane of the vagina was incised transversely immediately above the dusky red line of demarcation, and this incision was extended in depth until the peritoneum was reached. The peritoneal cavity was then opened anteriorly but sufficiently only in the first instance to allow of the introduction of the left forefinger. To prevent retraction of the peritoneum a fine

Digitized by Google

silk stitch was passed through the whole thickness of the tissues incised and was tied before the peritoneal sac was further opened. With scissors I carefully extended the incision to the right and left and again stitched the peritoneum to the mucous membrane of the vagina. The succeeding steps of the operation were similar to those adopted in vaginal hysterectomy, but it had to be borne in mind that the broad ligaments were displaced. After removing the tumour I closed the peritoneum with fine silk sutures. The ovaries were not removed. The temperature rose to 103° thirty-six hours after the operation, but the convalescence otherwise was most satisfactory and the patient made an excellent recovery.

The small sessile growth at the fundus was undoubtedly the exciting cause of the inversion in this case, yet it seems remarkable that it should have proved capable of this result after the menopause and so long after the birth of the last child. The tumour, although in a gangrenous state, was producing very little disturbance and the symptoms caused by it were so trivial that the patient did not seek advice until the odour of the discharge became practically unbearable. The peritoneal pouch, which measured about 5 in., showed no inflammatory change.

Gordon-square, W.C.

THE TREATMENT OF RINGWORM OF THE SCALP.

BY GEORGE STEELE PERKINS, M.D. EDIN., L.R.C.P. LOND., M.R.C.S. ENG.

MR. H. LYLE, in his paper on this subject in THE LANCET of Oct. 8th, points out the value of a simple method of treatment of chronic cases. For the past fifteen years I have treated every case of ringworm which has come under my care with chloride of sodium, and with complete success in every case. The first case in which I adopted this treatment was a chronic one of five years' standing. The child was well in three weeks and had no return. Many of the cases which I have attended since have been of a chronic character. The method I adopt is the following. Have some chloride of sodium finely powdered and then mixed with a little vaseline to make an ointment. The affected part having been shaved, rub this ointment in well night and morning until the place is sore; this takes from two to four days. Then apply some simple application to aid the healing of the part. When well from the soreness, the hairs will be found growing healthily and the tinea trichophyton destroyed.

Wimpole-street, W.

A CASE OF PUERPERAL SEPTICÆMIA.

BY HENRY K. DAWSON, M.D. DURH.

A HEALTHY countrywoman, aged twenty-five years, was attended by me in a normal labour on Oct. 25th, 1897. This (her fourth) confinement was of short duration and the placenta came away without any difficulty. The liquor amnii had escaped some days previously, since which time she had had, I was informed, more or less constant pain. On Oct. 27th there was a rigor and the temperature as recorded by a trained nurse rose to 102°F. During the next few days the temperatures were as follows: Oct 28th, morning, 103·8°; evening, 105·0°. Oct. 29th, morning, 101·4°; evening, 106·2°. Oct. 30th, morning, 103·0°; evening, 104°. Oct. 31st, morning, 102·0°; evening, 104·6°. Nov. 1st, morning, 103·4°; evening, 105·0°. From this date until Dec. 6th the temperatures showed a wide daily range, being almost invariably normal in the morning and varying from 101° to 103° in the evening. On and after Dec. 6th they were subnormal for five days and recovery was then established. The patient complained of slight pain in the left iliac region, becoming more severe for three or four days towards the latter part of the illness. The lochia remained healthy throughout, except that they occasionally contained some small shreds which were never offensive. The uterus continued large and tender to touch for some considerable time. Rigors were experienced every evening for nearly a month, of more or less severity. The tone of the pulse was good throughout, the rate rarely exceeding 100. There was no diarrhœa or sickness. The milk was not suppressed and the appetite remained good. The patient slept well, very little wasting took place, and the expression of the face could not be termed anxious. The patient's knees were never drawn up. On palpating the abdomen slight tenderness and some indistinct resistance were felt in the left iliac fossa. Per vaginam there was marked fulness in the left lateral fornix. The treatment adopted consisted of frequent intra-uterine douches of corrosive sublimate, the introduction of iodoform pessaries into the vagina, and 5 gr. doses of quinine every two or three hours. I regret that no bacteriological examination of the lochia or blood was made. Mr. Sumpter, of Sheringham, saw the case with me, and it was decided not to use anti-streptococcic serum, as the symptoms, with the exception of the temperature, were never urgent. The patient resumed her household duties at the end of February, 1898, with every appearance of good health. She, however, complained of some pain in the back.

LONDON HOSPITAL.

A CASE OF BLEEDING FIBROID IN WHICH ARREST OF THE HÆMORRHAGE AND SHRINKING OF THE TUMOUR FOLLOWED LIGATURE OF THE UTERINE ARTERIES.

(Under the care of Dr. G. E. HERMAN.)

THE anastomosis which exists between the branches of the uterine and ovarian arteries would have suggested that the collateral blood-supply after ligature of the uterine arteries would be great, but the effect in some cases at least produced by this ligature leaves no room for doubt that this collateral circulation is not established at all readily. Possibly some of the discordance in the results obtained in the treatment of fibroids by Martin's operation is to be explained by the ligature having included only one branch and not the main trunk of the uterine artery, as division occurs at some distance from the uterus. The two great arguments in favour of the operation are the absence of mutilation and the comparatively slight risk to life; these in themselves will be sufficient to render it a suitable operation in cases where patients or friends object to methods more likely to be followed by success. The effect in Dr. Herman's case was very striking and one such would outweigh many in which no benefit might result. For the notes of the case we are indebted to Dr. H. M. Rigby, resident accoucheur.

A patient, aged thirty-five years, was admitted into the London Hospital on Oct. 28th, 1897. She was married, but had never been pregnant. Her complaint was that for the last three years she had been "flooding" at intervals of about three weeks and for the last eight weeks she had been losing blood continuously. She complained also of pain in the right side and back. She had been treated for the hæmorrhage by ergot, but without benefit. On admission the patient was seen to be markedly anæmic. A moveable tumour composed of hard rounded nodules was felt rising out of the pelvis and reaching to within three fingers' breadth of the umbilicus. By bimanual examination this tumour was found to be continuous with the cervix and with other masses felt behind and at the sides of the cervix. The uterus was as freely moveable as was consistent with its size, and the cervix was low down. On Nov. 3rd, the cervix having been previously dilated with tents, the interior of the uterus was examined, but it was found that no tumour projected into the uterine cavity. The patient was advised that the best way of stopping the hæmorrhage was by an abdominal operation—either removal of the ovaries, or of the tumour, or of both, according to what the operator might judge to be safest after the abdomen had been opened. However, she absolutely refused to undergo any operation which would deprive her of the possibility of

Digitized by Google

pregnancy. Dr. Herman therefore decided to tie the uterine arteries. On the 10th a transverse incision was made through the vagina in front of the cervix, and with the fingers the bladder and ureters were separated from the uterus in front and the broad ligaments were opened up at its sides. When this had been done the uterine arteries could be felt pulsating. A ligature was passed over each from above downwards with an aneurysm needle and was tied. Oozing was checked by packing the wound with iodoform gauze. On Dec. 10th, one month later, the note was recorded that no hæmorrhage had occurred since the operation and that the uterus could be barely felt above the pubes. The patient menstruated after the operation about once in five or six weeks and not more copiously than was customary when she was in good health. She was seen last on July 5th, 1898, and then the uterus was not larger than at the end of the third month of pregnancy.

Remarks by Dr. HERMAN.—When the main artery of a limb is tied a collateral circulation is established so quickly that the nutrition of the part below is hardly affected. This consideration has made me think it so improbable that ligature of the uterine arteries would affect the nutrition of a fibroid that I have not before performed the operation, nor should I have done it in this case had not the patient refused more radical treatment. Ligature of the uterine arteries was first proposed and practised by Franklin H. Martin, of Chicago, in 1892, and the results reported from it[1] vary so considerably that it is difficult not to think that some of the observations must have been misinterpreted. But in this case there seems little room for doubt that dwindling of the fibroid and arrest of hæmorrhage have been produced by ligature of the uterine arteries, and should this be a frequent result of the operation it may prove very useful, for it has the obvious advantages of not mutilating the patient and of being attended with less danger than abdominal section.

DEVON AND EXETER HOSPITAL.

OLD TRAUMATIC DISLOCATION OF THE HIP; OPERATION; RECOVERY.

(Under the care of Mr. CHARLES E. BELL.)

A GREAT change has taken place during the last twenty years in the treatment of old dislocations of joints. The treatises on surgery used to contain time limits beyond which it was undesirable to attempt the reduction of a displaced bone, though cases were on record in which dislocations had been reduced several months after the infliction of the injury, but these were the exceptions until antiseptic surgery made it possible to operate on old dislocations without undue risk to the patient. At the present time every dislocation should be reduced (by an operation if necessary) unless the displaced bone has succeeded in obtaining sufficiently free movement in its new position or the age of the patient contra-indicates operative interference. In Mr. Bell's case the acetabulum was found to be filled with new tissue, and this would probably have prevented the head of the femur returning to its normal position, even if it could have been brought down by manipulation.

A boy, aged thirteen years, was admitted into the Devon and Exeter Hospital in November, 1897, with what proved on examination to be a dislocation of the head of the left femur on to the dorsum of the ilium. The patient, a strong, healthy lad, whilst he was playing football some five months previously was thrown as he was running; after this he was unable to walk and was therefore carried home. He was then put to bed, where he remained for about a fortnight. The hip was thought to be sprained and it was rubbed with liniment. When he was taken out of bed it was found that he could not stand, but nothing further seems to have been done until he was taken to the hospital nearly five months after the occurrence of the accident. As the leg was of no use to him, being much shortened and absolutely incapable of bearing any weight, the consent of the parents was obtained to the performance of an operation with the view of being able to return the head of the femur to the acetabulum. Accordingly, with strict antiseptic precautions, a free incision was made over the front of the great trochanter and all the muscles attached to this and to the shaft of the femur were separated subperiosteally as far as the lesser trochanter, and the head was lifted out of its new bed. The articular cartilage appeared to be quite good. The acetabulum was filled with new tissue and the remains of the capsular ligament. These having been removed with scissors and a scoop the cartilage appeared to be quite healthy. By steady traction and manipulation the head of the femur was replaced in the acetabulum, but it gave the idea of being somewhat too large for the cavity. All hæmorrhage having ceased the wound was washed out and closed with the exception of the opening for a drainage tube, which was put into the deepest part of the wound. A long splint was applied and the patient was put back to bed and a weight attached to the limb. The after-history was uneventful; there was practically no shock; some drainage of sero-sanguineous fluid occurred for a few days, but that was all. The temperature never rose and the boy slept and fed well. The splint was kept on for two months and then removed, the patient being allowed up on crutches. Since leaving the hospital he has been seen three or four times by Mr. Bell, the last occasion being on Aug. 8th, 1898. The boy had then perfect movement of the limb and could stand and walk well.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Hypertrophy of the Lung.—Fatal Summer Diarrhœa with Acute Enteritis.—Acromegaly.—Accessory Parathyroid Body.—Squamous-celled Carcinoma from the Trachea.—"Butter Cyst" of the Mamma.—Bony Nodules in the Tonsil.—Primary Sarcoma of the Scalp.

A MEETING of this society was held on Oct. 18th, the President, Dr. PAYNE, being in the chair.

Dr. NORMAN DALTON showed a specimen of Hypertrophy of the Lung removed from the body of a man, forty-five years of age, who was admitted to King's College Hospital dying from pneumonia of the right lower lobe. Externally the chest appeared to be normal, but on raising the sternum the right lung was found to pass across the mediastinum and to reach up under the left clavicle and into the left mammary region concealing the pericardium. The left lung was found behind, small, shrivelled, and airless. The hypertrophy was found to affect the middle and upper lobes, the right being bound down by adhesions. There was not much emphysema. The trachea bifurcated at the usual position. The left bronchus almost immediately narrowed. The lower branch could not be followed far beyond the constriction, but the upper could be followed as a mucous track for some distance. The space between the aorta and the bronchus was occupied by glands. Dr. Dalton held that this was not an undeveloped fœtal condition but was due to obstruction slowly produced. Most likely the obstruction had been due to enlargement of the glands already noticed.—Dr. CURNOW, under whose care the patient had been, said there had been nothing in the signs during life to suggest the abnormality.

Dr. F. W. ANDREWES showed specimens from a case of Fatal Summer Diarrhœa with Acute Enteritis. The case was of interest because the unusually severe enteritis found received a probable explanation in secondary streptococcus infection of the bowel. A girl, aged nineteen years, in previous good health, was attacked in August last by ordinary diarrhœa, mild at first but becoming more severe, till on the evening of the second day she was admitted to St. Bartholomew's Hospital in a state of profound collapse from which she never rallied. The stools were small, colourless, and like rice-water. She died about 56 hours from the onset. At the necropsy the only lesion found was an intense enteritis; the mucous membrane of the whole jejunum and ileum was of a vivid crimson colour and the solitary follicles stood out very conspicuously. There was no ulceration. The specimen shown had been prepared with formalin. Dr. Andrewes said that so intense an enteritis was not often seen in fatal "cholera nostras." Commonly there was little evidence of inflammatory change in the bowel to be seen after death. The causation of summer diarrhœa was still

Digitized by Google

unsettled, though it was almost certainly of microbic origin. The researches of Dr. Klein had given considerable grounds for associating his "bacillus enteritidis sporogenes" with the disease. Whether this be so or not there was in this case evidence of a streptococcic infection of the bowel which was probably superimposed upon the primary cause of the diarrhœa. Bacteriological investigation of the intestine and its contents gave the following results. The spirillum of Asiatic cholera was absent. Bacillus enteritidis sporogenes was present in a very virulent form, a culture being fatal in thirty-two hours to a guinea-pig which was injected. The chief organism present in the stools was a streptococcus. Sections of the intestinal wall stained by Gram's method showed in the necrotic mucosa small numbers of bacillus enteritidis sporogenes and streptococci. The streptococcus was obtained in pure culture and was not certainly identical with streptococcus pyogenes. Microscopic specimens of the intestinal wall and of the fæces were shown.

Mr. S. G. SHATTOCK exhibited an Acromegalic Skull from the collection of modern Italian crania purchased by the Royal College of Surgeons of England in 1870 from Dr. Liccolucci. Though placed by Sir William Flower amongst the normal crania it was noted at the time as massive and rugged. There was no difficulty in recognising it now as one of the acromegalic type. The changes in the bones were associated with very considerable enlargement of the pituitary fossa, proving the existence of a pituitary goitre. The parietal bones, where thickest, measured $\frac{1}{5}$ in. (2 cm.). In some examples of acromegaly the thickening had been classed as hypertrophic, but in the present case all distinction between tables and diploe was lost and the change could not be classed as one of hypertrophy in the strict or academic sense; its texture was indistinguishable from that of a calvarium thickened and sclerosed in the later stages of osteitis deformans. One of the most characteristic features was the lengthening of the face due especially to the enlargement of the lower jaw and notable prominence of the chin (cranium progeseum of anthropologists). About 40 per cent. of giants were stated (Maximilian Sternberg) to be acromegalic. Certain writers had alleged that gigantic stature was in all cases associated with, or due to, pituitary disease arising during growth—i.e., that all giants were acromegalic. This was untrue. There were normal and pathological giants as there were normal and pathological dwarfs. Besides the dwarfing of cretinism due to disease of the thyroid there were short-limbed dwarfs who were not cretinous, and dwarfs, thirdly, who were proportionally small throughout. In the College Museum there were the skeletons of two giants. One, 6 ft. 9 in., that of "Freeman the American Giant," presented obvious prognathism, but the bases of the skull were in no degree thickened and the pituitary fossa was not in the least enlarged, its antero-posterior diameter being only 1·4 cm. ($\frac{5}{8}$ in.). But the Irish giant (Charles Byrne or "O'Brian," 7 ft. 7 in.) the speaker viewed, with Dr. D. J. Cunningham, as an acromegalic. The lower jaw was massive and the chin was particularly prominent, the glabella was very projecting, and the cranial bones were dense and thickened. The pituitary fossa measured over 2 cm. antero-posteriorly. The capacity of the skull was 1520 cm.; that of the acromegalic Roman skull was 1500 cm., whilst that of the normal giant was by contrast 1630 cm. This Irish giant was not to be confused with that in the Museum of Trinity College, Dublin (Cornelius Magrath), which Cunningham in 1891 showed to be acromegalic. The Irish giant referred to in Sternberg's monograph was that in Dublin, not that in London.—Dr. CURNOW mentioned that there was a skull in King's College Museum supposed to be that of an Australian native. He himself, however, had always been doubtful as to its real nature and believed from its prognathism, thickening of the frontal bones, and the condition of the sutures that it was an acromegalic skull.

Mr. S. G. SHATTOCK also exhibited a specimen of Accessory Parathyroid in the Human Subject, with complete microscopic sections. The body was of about the size of a small pea, which was found loosely hanging from the lower region of the thyroid isthmus in a man, twenty-two years of age, who died from intussusception. Histologically this was a most perfect example of parathyroid tissue and consisted of columns of cells ramifying in a close capillary mesh and showing nowhere any trace of lumen or of colloid. Such accessory bodies were to be distinguished from accessory thyroids; they were accessory parathyroids. He was induced to show it in consequence of the importance the subject of parathyroid tissue had attained. In the thyroid of the adult he had seen small flattened islands lying at the surface and far removed from the situation of the parathyroids described in them by Sandström, and especially more recently by Welsh, the latter glands being two on either side at the lower part of the lateral lobes about the site of the inferior thyroid artery. The subject was complicated by the fact that at times in the lower animals, but not rarely in man, it had been found that the parathyroids contained also thyroid tissue. So unlike were the islands he had seen—e.g., on the anterior surface of the lateral lobe—that he could not help suspecting parathyroid tissue in man was more extensive than that comprised in the parathyroids alone.

Dr. LAZARUS-BARLOW showed the Trachea of a man, aged fifty-six years, into which a Squamous-cell Carcinoma had perforated. The point of difficulty had reference to the seat of origin of the growth. The growth was of about the size of a small Tangerine orange and lay obliquely in front of the trachea between the lower margin of the thyroid gland and the upper margin of the remains of the thymus gland. During life it was almost entirely covered by the manubrium sterni. The seat of perforation was in the middle line of the trachea about 1¼ in. above the bifurcation. There was strong probability that the growth was primary in this situation, firstly, because nodules found in the cervical glands—especially on the right side—were much smaller; and, secondly, because there was no new growth visible in the tongue, mouth, or œsophagus. Neither was the skin anywhere implicated. The possible explanations were that the growth had arisen either in connexion with an accessory thyroid body, or with a remnant of the thymus gland, or with the trachea, or with a fœtal remnant of squamous epithelium included in the deeper tissues during closure of a branchial cleft. Against the view that it was of thymic origin was the fact that no Hassall's corpuscles could be found in the peripheral part of the growth. Against the views that it arose in the trachea was the fact that its structure was undoubtedly that of a squamous-cell epithelioma. Against the view that it arose from a fœtal inclusion of squamous epithelium during closure of a branchial cleft was the impossibility of proving the point. On the whole, however, Dr. Lazarus-Barlow thought that the latter view was most probable.—Mr. SHATTOCK said that if the tumour were really primary it probably grew as suggested from a branchial cleft, although it was rather low down for such an origin. The lower branchial cleft was developed from the pharynx at one end and the skin at the other. Had the squamous epithelium any stratum granulosum, as would be the case if it arose from the epidermic end?—Dr. ROLLESTON thought that it was possible the tumour might have arisen from the track of the depression in the visceral arch, which led to the development of the thymus in which the squamous epithelial structures were normally found. He had shown some years ago a specimen of spheroidal-celled carcinoma removed from the neck in relation to which no primary tumour could be discovered, and a similar case had been mentioned by Mr. Bowlby.—Dr. LAZARUS-BARLOW, in reply, said that the trachea was deviated and so the tumour was not really as mesially situated as at first sight appeared.

Mr. BETHAM ROBINSON showed a specimen of "Butter Cyst" of the Mamma which was removed in October, 1897, from the breast of a married women, aged twenty-five years, who gave the following history. Fifteen months before, three weeks after her first confinement, she suffered from an "abscess" of the right breast in almost the same situation as the present swelling. The breast became large, painful, and tender, especially at the upper and outer part. The inflammatory mass was punctured twice, not incised, and a considerable quantity of pus (?) was drawn off. Soon after the abscess had apparently healed she began to notice a small lump about the centre of her right breast. This quickly reached to the size of a Tangerine orange and had remained so. There was rarely any pain in connexion with it and no discharge from the nipple. On admission the lump, which was circular in outline, elastic, and about 2 in. in diameter, was situated above the nipple and showed at its inner part the scars of the two punctures. It was not tender. The gland on the inner wall of the axilla was distinctly enlarged. The lump with a margin of healthy gland structure round was removed as well as the enlarged gland.

Digitized by Google

The swelling proved to be a cyst with smooth walls filled with a yellowish-brown semi-solid substance of the consistence of butter. On histological examination of the cyst-wall there were gland lobules to be seen embedded in some excess of fibrous tissue; the lining membrane was epithelial, flattened, chiefly in a single layer, and not granulation tissue. The cyst contents hardened on exposure to the air; with ether the main part (the fatty portion) was soluble; the undissolved part microscopically consisted of protoplasmic masses, apparently fatty epthelial cells without leucocytes, and with this could be seen sheaves of circular crystals, probably stearin. The condition, therefore, was a galactocele, but modified to this extent that the watery constituents had become absorbed, leaving only the more solid part behind. It was possible to get such retained products quite hard, dry, and friable, resembling very much old cheese. Such a case was shown by Mr. Wickins-Pitchford and recorded in vol. xlvii. of the Transactions, p. 250. Here the milk had been retained in dilatations associated with fibroid change in the breast and gradually lost all its watery elements; the "cheesy" material was proved to be chiefly fatty.

Dr. HUGH WALSHAM exhibited: 1. Bony Trabeculæ and Nodules in the Tonsil of a man, sixty years of age, who died from phthisis. There was nothing to indicate the condition during life. 2. Cartilaginous Nodules from the Tonsil of a young man also found after death. It seemed most likely that they were derived from some branchial cleft, but Dr. Kanthack, who had seen the specimens, regarded them merely as instances of metaplasia of fibrous tissue.—Mr. J. H. TARGETT mentioned that he had found bony nodules in the corium of the scalp.—Dr. ST. CLAIR THOMSON asked if the bone and cartilage might not come from the tip of the styloid process, which in some people reached right down to the tonsil.—Mr. SHATTOCK agreed that the nodules were derived from a branchial cleft and reminded Dr. St. Clair Thomson that the styloid process and its ligament represented one of the branchial clefts.—The PRESIDENT thought the cartilage and bone were most likely derived from some part of the skeleton, as suggested by Dr. St. Clair Thomson. Osteoma of the skin was very rare.—Dr. WALSHAM, in reply, said the nodules were multiple and so could not represent the tip of the styloid process.

Mr. P. DE SANTI exhibited specimens of Primary Sarcoma of the Scalp. The patient was a young woman. A lump was noticed in the right side of her scalp when she was a year old. They became more numerous, but varied in size for some years. They were removed in 1891, again in 1897, and in 1898, the growths having recurred, they were removed with the exception of two or three near the sterno-mastoid. The patient died a few months later from extensive secondary deposit in the lungs.

Dr. R. G. HEBB showed sections of Actinomycosis of the Tongue removed from a sailor sixty years of age. The lump was of the size of an almond, an inch behind the tip. It was excised and the centre was yellow and cheesy. Sections of the wall showed chiefly small-celled infiltration, but here and there were typical groups of the ray fungus.—The PRESIDENT remarked on the rarity of actinomycosis of the tongue in man, although it was so common in cattle.

CLINICAL SOCIETY OF LONDON.

President's Address. — Myositis Ossificans. — Congenital Cardiac Lesions in Mongolian Idiots.—Erythema Enematogenes.—Pin in the Vermiform Appendix.

THE first meeting of the present session was held on Oct. 14th, the President, Mr. LANGTON, being in the chair.

The PRESIDENT thanked the society for electing him to the chair a second time. He referred to the prosperous state of the society, which now had a membership roll of 588, and the financial position was fully secured. Of the 129 original members only 40 now remained. During the past year two original members had died, Sir Richard Quain and Dr. Ramskill. An index volume referring to the first 30 volumes of the society had been edited by Dr. Archibald Garrod and was a model of accuracy and completeness. The President presented the new volume of the Transactions of the Society and remarked on the value of the report on the antitoxin treatment drawn up by a committee under the presidency of Dr. Church. The society had always encouraged the observation and recording of facts. But the President wished to point out that observation required to be supplemented by skill in marshalling facts. In his later days Hunter insisted that theory should guide the record of observations. In their records observers should exercise a little scepticism both as to the accuracy of their own observations and as to the correctness of statements made by patients. Referring to the association between medicine and surgery the President said that there had been occasional efforts to separate them. At St. Bartholomew's Hospital in 1662, for instance, the governors decreed that "the apothecary do not prepare or dispense any medicines except such as be ordered by the physicians." Later a relaxation was made, the surgeons being allowed to prescribe mercurials and purges only. The papers read during the last session, especially those on abdominal diseases, showed how often the fields of the physician and surgeon overlapped. Referring to the question of the treatment of perforated gastric ulcer the President said that he thought all would agree that early operation gave the only chance. He preferred to sponge out solid matter as far as possible and then flush the abdominal cavity with sterilised water. He was inclined to think favourably of the proposal by Billroth and others to excise the ulcer before perforation if its presence could be diagnosed with any degree of certainty. This would especially refer to ulcers on the anterior wall. Deaths took place in considerable numbers in the London hospitals from this condition; the patients were usually young women or males of middle age. The operation itself would not now involve very great danger.

Dr. W. P. HERRINGHAM narrated a case of so-called Progressive Myositis Ossificans. The patient, a girl, now aged eight years, was shown as a living specimen to the society three years before by Mr. Owen Paget.[1] Rigidity was first noticed about the shoulders at two years of age. At five years of age swellings appeared in the back for which she saw Mr. Paget. The swellings were large at first, but disappeared under treatment. They were attached to the ribs and were probably fibrous in character. The shoulders were then rigid owing to ossification of the pectorals and latissimus dorsi and the head was fixed from rigidity of the sterno-mastoids, which were swollen. Microdactylia of the big toes was also noticed. At the present time the back had become more rigid so that the whole spinal column moved like a rod; a considerable bony prominence was found behind the left mastoid process; there were bony nodules springing from the ulna on both sides, which on the right arm limited supination; the thumb was small and imperfectly abducted; there was an exostosis on the first phalanx of the right middle finger. A pencil of bone was found in the right abdominal muscles running from the anterior superior spine of the ilium to the ninth costal cartilage and another was in the sheath of the right rectus abdominis. There had been pain lately about the right hip and its movements were not quite so free as those on the left side. The right biceps femoris tended to contract, but could be extended by force. Skiagrams showed the right shoulder-joint to be natural, the bony deposit being in the muscles alone. The deformity of the great toe was complex. The epiphysis of the first phalanx was thicker on the inner side; the first phalanx, somewhat tilted by this to the outer side, was itself thickened; the unequal phalanx was apparently joined to its head by synostosis, and was set on obliquely, pointing again outwards. The nail was perfect. The lesions of the disease were confined to the somato-pleural layer of the mesoblast, and in this to the bones, periosteum, and connective tissue only. The muscle was affected by secondary atrophy. Its pathology was uncertain. It was congenital and not hereditary. Of exciting causes injury alone had been sufficiently proved, and this in rare cases only. Males suffered more than females. There was no adequate evidence of any connexion with rheumatism or rheumatoid arthritis. The view of Pincus that it was a form of new growth appeared the most reasonable, and parallels might be drawn between this disease and multiple fibroma. It was not impossible that this anomalous disease might throw light on the pathology of tumour formation. The name was unfortunate, but must be retained until the pathology was more certain.—Mr. CAMPBELL WILLIAMS asked Dr. Herringham if he considered that the "chill" mentioned in the history was an attack of rheumatism. He had seen a case of an adult some time ago in Australia in which an attack of rheumatism preceded the appearance of the disease.—The PRESIDENT

[1] Transactions of the Clinical Society of London, vol. xxix., p. 221.

Digitized by Google

asked if the condition improved when the child was kept resting in bed.—Mr. W. G. SPENCER observed that ossification after rheumatism or injury was not so very rare. In Dr. Herringham's case, however, the disease appeared to be congenital, and this was confirmed by the deformity of the toes. He regarded the disease as a congenital irregularity of ossification. In certain birds this condition occurred normally, ossification extending into the tendons from the periosteum.—Dr. HERRINGHAM, in reply, agreed with Mr. Spencer as to the pathology. He thought the congenital irregularity in development which most regarded as the origin of tumour formation was perhaps a parallel condition. The ossification might occur, not only in muscles and tendons, but independently in the inter-muscular septa. He did not see why a chill should not start the disease in a person congenitally predisposed in the same way as an injury might, but he did not think there was any special relation to rheumatism. The patient's condition did improve when she was kept at rest.

Dr. ARCHIBALD GARROD briefly described 5 cases which had come under his notice in which Congenital Cardiac Lesions were met with in Association with the Mongolian Type of Idiocy. He expressed the belief that there was a specially close association between these two varieties of congenital defect although structural malformations of other kinds were not unfrequent in children with malformed hearts. Dr. John Thomson in a recent paper on the Types of Idiocy had mentioned the occurrence of congenital heart disease in three children of the Mongolian type, but inquiry of physicians with large experience of idiot children showed that the association was not a familiar one in asylums. This was very probably due to the failure of these children to survive to the age for admission to such institutions. Dr. Garrod's patients and those of Dr. Thomson were all below the age of five years. In several instances death occurred at an early age. With one exception the patients were girls. Congenital cardiac lesions were occasionally met with in idiots of other kinds, but in Dr. Garrod's experience much less frequently than in "Mongols."—Dr. A. M. GOSSAGE mentioned a case in which there were signs of congenital heart disease at the age of eight months and later the child showed the typical Mongolian type of idiocy.—Dr. GUTHRIE had examined the heart in two cases of the kind described by Dr. Garrod. One was that of an infant, eight months old, who had a loud systolic murmur but was not cyanosed. She became dropsical before death and it was found that there was an imperfect septum ventriculorum and a patent foramen ovale. In the second case the right side of the heart was hypertrophied and there was a cribriform opening at the upper part of the ventricular septum. He agreed with Dr. Garrod that the children usually died before being old enough to enter the idiot asylums.

Dr. G. F. STILL read a paper on Erythema Enematogenes (Enema Rash) in Children. Very few cases of enema rash in childhood had been recorded, and although this variety of erythema was of little significance *per se* it became of considerable importance in children, inasmuch as it was very easily mistaken for some of the specific fevers to which childhood is particularly exposed. The rash had a characteristic appearance and course, as was apparent from a study of 26 cases which had occurred at the Hospital for Sick Children, Great Ormond-street. There seemed to be no reason to doubt the causal relation of the enema to the rash. In some children repetition of the enema had been followed repeatedly by the rash. Usually a bright red patchy erythema appeared, especially on the front of the knees, the backs of the elbows, the buttocks, and the face; in some cases, however, the rash was scarlatiniform, or the two forms might be combined. It appeared most often from 12 to 24 hours after the enema, and lasted usually from 24 to 48 hours; there was very rarely, if ever, any constitutional disturbance; the amount and time of retention of the enema and the duration of the preceding constipation did not seem to affect its occurrence. The rash occurred most often after a first enema. Children over six years of age seemed more liable to it than younger children, but it occurred in one case at two years and three months. Scarlet fever, rötheln, and measles were the exanthems for which an enema rash was most likely to be mistaken. The absence of constitutional symptoms, of sore throat, coryza, and pyrexia, and often slight differences in the character and distribution of the rash, together with the occurrence just after an enema, might serve to differentiate the enema rash. There was some evidence that desquamation might occasionally follow an enema rash, making the diagnosis from scarlet-fever still more difficult. It seemed highly probable that a certain number of the cases of so-called "surgical scarlet fever" were the result of enema given before operation. The erythema must be regarded as the result of a vaso-motor dilatation, but how this was produced was uncertain. Three possible explanations suggested themselves: (1) absorption of some toxic substance from the soap of the enema, possibly from the fats or the resins used; (2) absorption of some fæcal toxin, thrown into solution by the enema; and (3) a reflex effect on the vaso-motor centres. Arguments might be advanced in favour of each theory, but on the whole it was perhaps most reasonable to regard the rash as due to a vaso-moter change produced by absorption from the intestine of some constituent of the enema or of the fæces. Further observations were necessary before it could be decided from which of these sources the toxin was absorbed.

Mr. CHARTERS SYMONDS briefly described a case of a Foreign Body in the Vermiform Appendix. The patient, a young woman, was admitted for a tender swelling in the right inguinal region. This was diagnosed as a strangulated hernia containing omentum, although the medical man who had first seen the case had looked on it as an inflamed inguinal gland. On opening the sac of the hernia, which was an inguinal one, an inflamed appendix was found therein. This was found to contain a pin with a glass head. This and the appendix were removed and the patient subsequently did well. Mr. Symonds brought the case forward since true foreign bodies in the appendix were rarely met with, most of the classical instances of cherry stones and date stones being merely instances of calcareous concretions.—The PRESIDENT said that the presence of the vermiform appendix in a hernial sac was not very uncommon and was more often met with in inguinal than in femoral hernia. The condition as described suggested a cystic collection in the canal of Nuck, but such cysts were not attended by the severe symptoms met with here. He had seen two genuine cases of foreign body in the appendix. In the first a pin was found and removed and the patient did well; in the second a needle caused the formation of an abscess in connexion with the appendix.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Some Points in the After-treatment of Cases of Abdominal Section.

A MEETING of this society was held on Oct. 13th, Mr. F. BOWREMAN JESSETT, Vice-President, being in the chair.

The following specimens were exhibited:—

Mr. CHRISTOPHER MARTIN (Birmingham): (1) Bifid Uterus with Retention of the Menses; and (2) Myoma of the Round Ligament.

Mr. R. H. HODGSON: Fibro-cystic Disease of the Uterus.

Dr. ARTHUR GILES: Large Cervical Myoma, weighing 7 lb., in the broad ligament.

Dr. J. MACPHERSON LAWRIE (Weymouth): (1) Uterine Fibroid complicated by Ovarian Cystoma; and (2) Fibroids removed by Myomectomy.

Dr. FREDERICK EDGE (Wolverhampton): Carcinoma Uteri removed by Vaginal Hysterectomy.

Mr. JESSETT: (1) Two specimens of Carcinoma Uteri, one complicated by fibroids, removed by vaginal hysterectomy; and (2) Cyst removed from the Transverse Meso-colon.

In the discussion on these specimens Dr. C. H. F. ROUTH, Dr. HEYWOOD SMITH, Dr. R. T. SMITH, Dr. GEORGE KEITH, and Mr. CHARLES RYALL took part.

Mr. CHRISTOPHER MARTIN read a paper on Some Moot Points in the After-treatment of Cases of Abdominal Section. He laid stress on the importance of preventing complications by care in the preparation of the patient, in the performance of the operation, and in the attainment of perfect asepsis. He said it was unnecessary to keep the patient rigidly on her back for 48 hours. The dressings should be simple, dry and absorbent, and aseptic. Wet dressings favoured suppuration and powders formed unpleasant crusts. For closing the abdominal wall he used interrupted sutures of silkworm gut passed through the whole abdominal wall. He disliked buried sutures. The sutures should not be removed till the tenth or twelfth day. He only drained in septic cases or

Digitized by Google

where there was much oozing. A little clean blood did no harm. He advocated iodoform gauze as a drain in preference to glass or rubber tubes. It was better to drain through the posterior fornix than through the abdominal wall. A hypodermic injection of morphia was advisable immediately after the operation as also in cases of great prostration and restlessness. He strongly recommended the purgative treatment of peritonitis, preferably calomel and salines, and discussed the mechanism of their beneficial action. He advised the early administration of bland fluids after the operation; it was cruel and harmful to withhold fluids for 48 hours. In vaginal sections he said the vagina should be packed with iodoform gauze and this should be left in till the seventh day. It was unwise to douche for at least a week after the gauze had been removed for fear of forcing the vaginal discharges into the peritoneum. Lastly, an abdominal belt should be worn for at least two years after every abdominal section. The discussion on this paper was adjourned to the next meeting.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Presidential Address.

A MEETING of this society was held on Oct. 14th, the President, Dr. E. GWYNN, being in the chair.

The PRESIDENT delivered an address on the Medical Officer of Health as a Public Teacher. Lord Beaconsfield, then Mr. Disraeli, in the electoral campaign of 1874, declared the public health to be the question of the day, and in the motto, *Sanitas sanitatum, omnia sanitas*, gave a watchword to his party which produced a succession of statutes beginning with his Public Health Act of 1875 and ending with that for London under Lord Salisbury's administration in 1891, each being a consolidation of, and improvement on, previous legislation. These acts, though fragmentary and imperfect, had been productive of much good. The two great religious legislators, Moses and Mahomed, inculcated personal cleanliness on their followers, but in the dark ages its neglect was regarded as a virtue and a distinctive mark of Christians. In our days, again, the sanitary reformer was the man of science as represented by the medical officer of health—a creation of the Act of 1855. An address by Sir B. W. Richardson in 1876 on "The City of Hygieiopolis" had aroused the public interest in sanitary problems, but the greatest impulse to practical results was given by Lord Salisbury's own article in the *National Review* in 1883 on the "Housing of the Working-classes." But the education of public opinion devolved on the medical officers of health, created by the Act of 1855, and whose appointment was made compulsory everywhere by that of 1875. Able, however, as a large proportion of these officers were, the multifarious nature of the routine duties imposed on them tended to give them the character of permanent officials and left them little leisure for other work. The necessity for the education of the public was evident from the fact that England, which had been the pioneer in practical sanitation, had not retained the lead but was being left behind in many respects by some other countries. He need but allude to the promotion of bacteriological and other scientific research, which, in the absence of the State aid so liberally granted on the continent, was here left to private generosity and effort; the "tremendous experiment," as Lord Lister had called it, of the abandonment of compulsory vaccination at a time when other nations were one by one following the example of Germany in requiring universal vaccination and revaccination; the ignorance of the principles of ventilation shown by the foul air of the law courts, theatres, schools, and churches; the general apathy as to the dangers of tuberculous milk and flesh,—in all of which we were behind other peoples. Other subjects on which the medical officer of health had great opportunities for teaching and leading public opinion were the housing of the working classes, not only in the slums and tenement dwellings of the older quarters of London, but in the thousands of jerry-built houses, springing up on all sides in the outskirts of the metropolis, destined to fall into dilapidation and become suburban slums in the course of a few years, these being the direct result of the vicious system of short ground leases and inefficient official control; while the consequences of these insanitary conditions were a high infant mortality, the miserable physique and demoralisation of the survivors, immorality, and crime. Then there was the pollution of the air by smoke tending to a high mortality from respiratory diseases. By how many sanitary authorities were the Smoke Acts strictly enforced? On all these questions and many others the medical officer's duty was to inform the community, but that he should be capable of fulfilling his true mission of their teacher, adviser, and leader it was necessary that he should enjoy more leisure and authority and that his salary and position should be such as to attract the best and ablest men in the profession. Meanwhile he urged his fellow officers to take a wide and lofty view of their vocation as embracing the welfare, physical and moral, of the entire community and to adopt as their motto, *Homo sum, humani nihil a me alienum puto.*

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

Presidential Address.—Annual Report.

THE annual meeting of this society was held on Oct. 12th in the Medical Library of University College, Bristol, Dr. Shaw, and afterwards Dr. Roxburgh, being in the chair.

Dr. R. ROXBURGH, in giving his Presidential Address, referred to a number of fascinating topics which at the present moment faced the pathologist, and some of which seemed on the verge of complete elucidation. The President then proceeded to deal with the Disillusions and Disabilities of Private Practice. He compared the ideals of the young and enthusiastic medical graduate with the difficulties which met him in maintaining these and in preserving a high scientific and ethical standard where his object was primarily to earn a livelihood. He pointed out that it was from the "commercial" side of practice that temptations arose to unprofessional acts and he appealed to the teachers of the Bristol Medical School to set a high ethical ideal before their students.

Mr. PAUL BUSH (honorary secretary) read his annual report, which showed a balance in hand of £47 on the ordinary account and of £103 on the Journal account. He referred to the loss the society had sustained by the death of Dr. H. Marshall and Mr. Augustin Prichard.

Dr. B. ROGERS (editorial secretary) read his report, which showed a deficit of £5 on the Journal for the year.

The honorary librarian (Mr. L. M. GRIFFITHS) read his report, which showed a balance in hand of £50; he mentioned that there were now 7180 books belonging to the society and that the Bristol Medical Library now contained nearly 19,000 volumes and was in receipt of 204 current periodicals. He made a long and clear statement as to the present condition of the library and intimated that after this year he would be unable to continue to be honorary librarian.

Dr. J. G. SWAYNE proposed and Mr. HANDCOCKE WATHEN seconded, and it was carried, "That Mr. L. M. Griffiths be thanked for his long services and that the report be adopted."

Dr. J. E. SHAW the retiring President, in supporting this motion, said it was the wish of all the members of the society that Mr. Griffiths should continue in office, a post he had so long held with such great benefit to the society and to the users of the medical library. He further mentioned that the excellent condition of the medical library was largely due to the energy and knowledge of Mr. Griffiths.

Mr. W. H. Harsant was elected President-elect; Mr. Paul Bush was re-elected honorary secretary; and Mr. L. M. Griffiths was re-elected honorary librarian. The following were elected to serve on the committee: Dr. Michell Clarke, Mr. J. Dacre, Dr. D. S. Davies, Dr. B. Rogers, Mr. Munro Smith, and Dr. H. Waldo. Mr. L. M. Griffiths, Dr. G. Parker, and Mr. J. Taylor were elected to serve on the Library Committee. Mr. W. Roger Williams was elected a member of the society.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Election of Officers.—Exhibition of Specimens.

A MEETING of this society was held on Oct. 12th, Mr. C. E. RICHMOND, President, being in the chair.

The annual reports of the treasurer and committee were received and the following office-bearers elected for the

Digitized by Google

session 1898-99:—President: Dr. R. B. Wild. Vice-Presidents: Mr. J. Collier and Dr. E. S. Reynolds. Treasurer: Dr. T. A. Helme. Secretary: Dr. T. N. Kelynack. Committee: Dr. A. Brown, Dr. W. E. Fothergill, Mr. J. E. Platt, Dr. W. Milligan, Dr. F. C. Moore, Mr. W. A. Renshaw, Mr. J. W. Smith, and Mr. W. P. Stocks. Auditors: Mr. W. A. Hooton and Dr. E. J. Sidebotham.

The following card specimens were exhibited:—

Mr. STANMORE BISHOP: (1) Tuberculous Kidney; (2) Pyosalpinx, with Ovary converted into Thick-walled Abscess; (3) Pyosalpinx; (4) Chronic Metritis with Mucoid Polypus; (5) Ectopic Gestation removed before Rupture; (6) Encysted Hæmatocele of the Cord; (7) Tubo-ovarian Abscess; and (8) Fibro-cystic Uterus.

Dr. BLACKWELL: Cured Aneurysm of the Abdominal Aorta.

Dr. VIPOND BROWN: Calculus formed around a Hairpin.

Professor DELÉPINE: Apparatus for taking Photographs of Morbid Specimens under Water, with demonstration on the screen of results obtained.

Dr. DRESCHFELD: Syphilitic Liver.

Dr. KELYNACK: Medico-legal specimens—(1) Pharynx and Larynx blocked by Partially Masticated Meat; (2) Stomach from a case of acute Arsenical Poisoning; (3) Stomach from a case of acute Carbolic Acid Poisoning; and (4) Stomach from a case of Nitric Acid and Mercury Poisoning.

Dr MILLIGAN: Microscopic sections of—(1) Tuberculous Growth of the Septum Nasi; (2) Maxillary Antral Polypus; (3) Sarcoma of the Septum Nasi; (4) Sarcoma of the Soft Palate; and (5) Papilloma of the Uvula.

Dr. MOORE: Some Mammary Tumours.

Dr. STODDART: (1) Cast of a Stomach formed during life by ingestion of string, hair, &c.; (2) Chronic Ulcer of the Stomach simulating cancer during life; (3) Lymphadenomatous Spleen; and (4) Microscopical Sections of the Spinal Cord from a case of acute Suppurative Peritonitis.

Dr. WILD: Photographs and Microscopic Preparations from a case of Lichen Planus Verrucosus.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

THE first meeting of the session was held in the Royal Infirmary, Newcastle-upon-Tyne, on Oct. 13th, Mr. H. HIND, President, being in the chair.

The following office-bearers were elected for the ensuing session:—President: Dr. Limont. Vice-Presidents: Mr. Hind, Mr. Rutherford Morison, Dr. G. R. Murray, and Dr. R. S. Peart. Honorary Secretaries: Dr. T. Beattie and Dr. A. M. Martin.

Mr. WILLIAMSON introduced a patient recovering from Orbital Thrombosis. Proptosis had remained limited to the right eye which was "spoilt." No septic focus had been discovered. He also recited a series of five cases of orbital thrombosis arising from trivial face injuries.

Dr. BEATTIE recounted a case of Cavernous Sinus Thrombosis proved by exclusion, post mortem, to have been due to facial erysipelas, and two others proved on necropsy to have resulted from middle-ear disease, the most frequent cause.—The PRESIDENT commented upon the rarity of this condition as a sequela to the very frequent septic affections of the nose.

Mr. MORISON brought forward a case of Orbital Sarcoma for comparison with Mr. Williamson's case.

Dr. G. R. MURRAY introduced: 1. A case of Thoracic Aneurysm showing Dilatation of the Superficial Arteries in the Chest-wall. A deep impulse was felt posteriorly to the left of the spine and a loud systolic bruit was heard over a wide area, being especially intense over the upper part of the spine. A marked peculiarity of the case was the almost complete absence of pulsation in the abdominal aorta and in the femoral arteries. 2. A case of Thoracic Aneurysm pointing in the Third and Fourth Intercostal Spaces immediately to the left of the Sternum. 3. A patient with Aneurysms of the Innominate Artery and of the Abdominal Aorta.—Dr. DRUMMOND referred to the difficulties of the first case and expressed his opinion that it was one of fusiform dilatation of the thoracic aorta with the formation of laminated clot which had been displaced and partially occluded the descending aorta. The second case, he thought, did not spring from the ascending arch but from the anterior surface of the descending aorta.

Dr. MURPHY showed: 1. A child, aged ten months, from whom he had successfully removed a large Cranial Meningocele. The child was now developing hydrocephalus. 2. A boy, aged six years, very anæmic, with a very large spleen and a liver slightly enlarged. He asked for a diagnosis and suggestions for treatment.—Dr. BEATTIE, after examining the blood, reported that there was no leucocytosis. The case was therefore not one of leukæmia; he would rather consider the splenic enlargement secondary to the anæmia.—Dr. DRUMMOND said the case answered the description of so-called "splenic anæmia." He thought it essentially one for medical treatment.—Dr. PLUMMER and Dr. OLIVER also took part in the discussion.

Professor OLIVER showed a patient recovering from Caisson Disease. The man had worked as a sinker at the construction of the piers of a bridge which was being built over the Tyne at a depth of 75 ft. below high-water level and at an atmospheric pressure of 35 lb. to the square inch. He had severe cramping muscular pains, with rigidity and paresis of the arms and legs, and a tendency to syncopal attacks. At the onset he had suffered from epistaxis and deafness.—The PRESIDENT asked whether hæmaturia or emphysema of the lungs had occurred in this case, and was answered in the negative.

The following specimens were exhibited:—

Dr. MURPHY: Appendix removed seven hours after the onset of the symptoms. The patient had made an uninterrupted recovery.

Mr. WILLIAMSON: Liver and Duodenum, showing a large communication between the fundus of the gall-bladder and the duodenum with a large facetted gall-stone *in situ*. Another large facetted stone had been removed from the small intestine by operation, where as an enterolith it had caused acute intestinal obstruction.

Dr. DRUMMOND: Congenital Cystic Kidneys removed from a woman, aged forty-five years, being the third member of the same family who had died in adult life from this disease, diagnosis confirmed by necropsy. He stated that he had at present under observation two members of another family suffering from the same disease.—Mr. ANGUS, Dr. BEATTIE, Mr. MORISON, and Dr. DRUMMOND discussed the developmental origin and subsequent pathology of the condition.

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held in the University College, Dundee, on Oct. 7th, Dr. J. Mackie Whyte, Vice-President, being in the chair.—Dr. McGillivray showed a case of Paralysis of the Right Cervical Sympathetic with well-marked symptoms of Unilateral Anhidrosis, Myosis, Ptosis, Enophthalmos, and Heterochromia. No direct cause could be ascertained except the vague history of an injury to the cervical vertebræ, which probably also accounted for the pain on deep pressure over the spinous processes of the third and fourth cervical vertebræ. Dr. McGillivray also discussed certain points in connexion with the treatment of corneal ulceration, such as the relief of photophobia and blepharospasm for the purpose of restoring the normal processes of nictitation and lacrymation and also the normal corneal temperature, &c.—Dr. Stalker read notes of three cases of Needle Swallowing and discussed the treatment.—Mr. Greig read a paper on the Infectivity of Venereal Warts in which he set forth that a fourth venereal disease should be recognised. Out of 330 venereal cases of his own taken at random 14 had venereal papillomata, 9 of which had absolutely no evidence or history of any other venereal trouble or any signs of balanitis, &c. Mr. Greig gave an example of a husband having infected the wife with venereal warts and also an example where the husband infected the wife and the wife infected her child. He did not think that it would be put down to the discharge when both are present, as one often finds the discharge present without any warts. The incubation period he thought was about four weeks.—Dr. Mackie Whyte spoke of cases he had seen in the parochial hospital and treated successfully with salicylic acid and collodion.—Dr. Mackie Whyte read notes of a case of Tricuspid Stenosis in a woman, aged thirty-seven years, whose trouble had commenced with an attack of endocarditis at the age of ten years. Mitral and aortic stenosis developed and this was evidently followed by tricuspid, as was shown by the condition of the valves at the post-mortem examination. The right auricle

Digitized by Google

of the heart (which was shown at the meeting) was greatly enlarged and hypertrophied, the right ventricle had thinner walls than normal, the left auricle was somewhat hypertrophied, and the left ventricle showed thickening of the wall (⅛ in.), but no dilatation. Dr. Whyte also spoke of a case he had attended several years ago of pure tricuspid stenosis.

BIRKENHEAD MEDICAL SOCIETY.—The inaugural meeting of this society for the session 1898–99 was held on Oct. 14th and was well attended. Dr. Francis Johnston having resigned the office of President Dr. H. Nazeby Harrington was unanimously elected to the position and Dr. Joseph Blood to that of Vice-President. The President (Dr. Harrington) gave an inaugural address on the Association of Medicine with Literature in England, pointing out some of the facts connected with the lives of members of the medical profession who had become prominent in the world of letters from the time of Thomas Linacre down to that of Conan Doyle, special attention being drawn to the medical part of their lives and the influence that their medical training had upon their literary work. Whilst most of the medical *littérateurs* were touched upon the following were spoken of at greater length: Linacre, Sir Thomas Browne, Sir Samuel Garth, Sir Richard Blackmore, Smollett, Akenside, Goldsmith, Crabbe, and Keats.—A hearty vote of thanks, proposed by Dr. Sydney Marsden, seconded by Dr. Harris, and supported by Mr. Vacher, Mr. Shears, Dr. Temple, and Mr. Laird Pearson, was given to the President for his able address.—The President replied.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the forty-third session was held on Oct. 14th at the Royal Kent Dispensary, Greenwich-road, S.E. Dr. E. H. Ezard, Vice-President, occupied the chair.—The treasurer's balance-sheet and the annual report were adopted and several new members were elected.—Mr. Ernest Clarke read notes of cases of Foreign Bodies in the Orbit in which no external wound was visible.—Dr. Toogood, Mr. Hartt, and Mr. Joscelyne discussed the paper.—Dr. George Herschell then gave a demonstration on Intra-gastric Instruments, including Turck's Gyromele and the Intra-gastric Needle Douche.—Dr. Morgan Dockrell showed cases of Urticaria Pigmentosa and Syphilis.—Dr. Toogood showed a case of Tuberculous Arthritis in a child which was gradually improving.—The following officers were elected:—President: Dr. Morgan Dockrell. Vice-Presidents: Dr. Edward H. Ezard and Mr. Charles J. Parke. Council: Dr. George Herschell, Mr. Arthur E. Joscelyne, Dr. John Mackern, B.A., Dr. Thomas C. Meggison, Dr. Robert E. Scholefield, Dr. Patrick C. Scott, and Dr. Septimus Sunderland. Treasurer: Mr. John P. Purvis. Secretary: Dr. John P. Henry. Librarian: Dr. H. Bowen Williams.

NEWPORT MEDICAL SOCIETY.—The annual meeting of this society was held on Oct. 5th, the retiring President, Mr. O. E. B. Marsh, occupying the chair. The honorary secretary read his report on the work of the society during the past year and this was discussed and approved. The election of officers for the ensuing session was then proceeded with. Mr. H. E. Williams was elected President, Mr. C. Brooke Gratte was elected Vice-President, and Mr. W. Basset was re-elected honorary secretary. Mr. H. B. Seddon and Mr. B. W. Gowring were elected to the two vacancies on the committee. The retiring President then vacated the chair in favour of the President, who returned thanks to the members for his election, and in the course of a few remarks commented upon the satisfactory position of the society and of the usefulness of the same.—A case of Molluscum Contagiosum was shown by Dr. T. Morrell Thomas and Mr. Marsh showed a specimen of small Ovarian Cyst removed by him, with notes of operation, &c.

WEST PENRITH MEDICAL SOCIETY.—A medical society has been formed comprising those medical men practising in the Land's End district under the title of the West Penrith Medical Society. The first meeting was held at the West Cornwall Infirmary on Oct. 12th, when Dr. J. B. Montgomery was elected President and Mr. W. S. Bennett Vice-President. Mr. J. Symons and Mr. H. M. Montgomerie were elected on the committee and Mr. A. R. F. Evershed was elected Secretary. After the election Dr. Hugh M. Montgomerie read a short paper on Infective Endocarditis, illustrating his remarks with the heart from a case which had recently been in the infirmary.

Reviews and Notices of Books.

Manual of Ophthalmic Surgery and Medicine. By WALTER H. H. JESSOP, M.A., M.B. Cantab., F.R.C.S. Eng., Ophthalmic Surgeon to, and Lecturer on Ophthalmic Medicine and Surgery at, St. Bartholomew's Hospital, &c. London: J. and A. Churchill. Crown 8vo. Pp. 469. Price 9*s.* 6*d.*

MR. JESSOP has in the work before us written a manual which will prove very serviceable to the student. He has taken for granted that those who will use it are fairly familiar with the anatomy and physiology of the eye and that it is unnecessary to do more than recall to their memory those facts which have a direct bearing on the pathology of the several tunics and humours. Thus under the head of Diseases of the Choroid there is a short introductory paragraph, not exceeding half a page, which describes its position, the layers of which it is composed, with the nervous and vascular supply, but, of course, with no details of the several constituents. So with the Diseases of the Retina, the structure of the retina is relegated to a short note; but the points which it is useful for a student to know, as the yellow spot and the disposition of the vessels, together with the origin, course, and arrangement of the fibres in the optic nerve, are given more fully. The style is throughout plain and intelligible and where a description of an operation is given, such as that of extraction of the lens in cataract or that of ectropion or tenotomy, Mr. Jessop expresses himself both with brevity and clearness. In the treatment of cataract he states that when the patient is not suffering from cough or any disease which necessitates straining he operates without an iridectomy, but in cases of incomplete or over-mature cataract he prefers an iridectomy owing to the difficulty of removing the soft lens substance without bruising the iris. He appears to prefer the 3-millimetre corneal flap operation. In speaking of herpes ophthalmicus Mr. Jessop states that he has found the best means to relieve the neuralgia and formication which persist after the vesicles have disappeared to be a mixture of chloroform and eau-de-Cologne. He, however, does not mention a method of treatment which has been found to be very effective—the passage of a constant current of electricity.

In the treatment of sarcoma and malignant growths their removal with, if necessary, that of the eye and the contents of the orbit is recommended, and after the hæmorrhage has been stopped by pressure it is suggested that chloride of zinc on strips of lint may be plastered round the sides of the orbit and the rest of the cavity filled up with cotton-wool. It is indeed added that "the effect of this treatment is that the periosteum and frequently a layer of bone exfoliate," and that "this operation is always followed by severe reaction." But the proceeding is a dangerous one and we have known a fatal result to follow from the chloride of zinc penetrating the cranial cavity and eating away the walls of the cavernous sinus.

Mr. Jessop is of opinion that sympathetic ophthalmitis is probably of microbic origin, though he admits that the exact method of transmission from the exciting to the sympathising eye is still uncertain. When sympathetic ophthalmitis has definitely commenced, although its course can be but little altered by excision of the exciting eye, yet if this eye be blind or only have perception of light it should, he thinks, be straightway removed, and in such cases he would never do a partial operation as abscission or evisceration, and we consider this to be sound practice.

Although we agree generally with the opinions held by Mr. Jessop, we think that he does not counsel wisely when in speaking of tenotomy he observes that the operator may increase the effect of the operation by dividing freely the

Digitized by Google

capsule of Tenon near the tendon or by rotating the eyeball forcibly by the forceps in the opposite direction to allow the tendon to slip backwards. The last proceeding is very uncertain in its effects and the free division of the capsule of Tenon we take to be the cause of many bad results. If division of the tendon at its insertion be insufficient to rectify the defect, it is better to proceed at once, as indeed he himself recommends on another page, to advance the opposite tendon. Extensive opening of the capsule of Tenon should never be practised.

The subjects of Refraction and Accommodation are briefly dealt with, but the practitioner will find in the chapter devoted to them all that is necessary to enable him to select the requisite glasses either by direct examination by means of the ophthalmoscope or by retinoscopy.

The chromo-lithographs are eight in number arranged on four plates, and give representations of the normal disc and of the following diseased conditions: albuminuric retinitis, disseminated choroiditis, retinitis pigmentosa, and papillitis; post papillitic atrophy; glaucoma and myopic crescent. Though not equal to the best foreign lithographs in colour they show very well the conditions which they are intended to represent. There is also a reproduction of Professor Holmgren's colour-vision plate giving the confusion tints. The woodcuts, which number 104, are well executed. There are remarkably few typographical errors. Altogether the work will hold its own against the several treatises of about the same size which have appeared in English and foreign tongues and we have great pleasure in recommending it to all who are about to spend three or six months in the ophthalmic wards of a hospital. With this book in their hands and daily observation of ophthalmic cases they will learn much that they will find useful in practice.

Elements of Histology. By E. KLEIN, M.D., F.R.S., and J. S. EDKINS, M.A., M.D. Revised and enlarged edition. London, Paris, New York, and Melbourne: Cassell and Co. 1898. Pp. 488. 296 Illustrations. Price 7*s.* 6*d.*

THIS valuable work is so well known to students that a new edition embodying recent discoveries is sure of a welcome. The book shows signs of careful revision throughout and many of the chapters have been completely rewritten. There is a practically new introductory chapter on the Structure and Life of the Individual Cell, and a full account is given of the minute structure of the nervous system as revealed by the staining processes elaborated by Weigert, Golgi, and Ramon y Cajal. The structure of the nerve cell revealed by Nissl's staining method is, however, not referred to. This section is admirably illustrated. Many other parts have been expanded to introduce the latest teaching. Dr. Klein and Dr. Edkins have wisely introduced photography largely for purposes of illustration, and the results, if less distinct than the older semi-diagrammatic drawings, are much truer to nature and correspond more closely with the preparations which the student will have to examine for himself. The section on the Blood hardly takes full account of the recent work of Ehrlich and others, but what is given is clearly written and well illustrated. Students could not have a better guide in their histological work and we have no hesitation in strongly recommending this edition.

Clinical Observations on 2000 Obstetric Cases. By G. PORTER MATHEW, M.D. Cantab. London: Simpkin, Marshall, and Co. 1898. Pp. 71. Price 2*s.*

CAREFULLY recorded clinical observations upon cases of labour are of the greatest possible value in enabling us to come to a conclusion as to the merits of the various methods of treatment advocated in abnormal cases of delivery. Dr. Mathew has analysed the cases under his care at Queen Charlotte's Hospital, at St. Mary's Hospital, and in private practice with great industry and care, and the results are of much interest. He has been perhaps a little too ready to lay down rules of treatment from what is after all a relatively small experience, although a very valuable one owing to the careful manner in which the results have been recorded.

In cases of unreduced occipito-posterior presentations he advocates early rotation of the occiput forwards per vaginam. We are inclined to think that many of these cases can be equally well treated by rotation of the child's body through the abdomen without the introduction of the hand into the vagina, and this is certainly, when possible, the safest and best method of treatment.

Dr. Mathew's remarks upon the varieties of a prolonged first stage are of value, and we can fully confirm from our own experience his recommendation of chloroform in those cases where the action of the uterus is almost continuous without any appreciable dilatation of the cervix and where the subjective distress is very great. The method of saving the perineum by the use of axis traction forceps, of which Dr. Milne Murray is so warm an advocate, is an exceedingly good one, although there are undoubtedly cases in which it is quite impossible by any means whatever to prevent a rupture. No doubt Dr. Mathew will sooner or later meet with such a case, although his results of 21 consecutive primiparæ delivered by axis traction forceps under chloroform without a single laceration of the perineum are exceptionally good. The author is in error in thinking that as regards sapræmia and the evolution of septicæmia the theory of symbiosis has not been put forward. It is, and has been for some time, a matter of current teaching, at any rate at one of the metropolitan medical schools, and we have no doubt that it is taught at others. Obstetricians owe Dr. Mathew a debt of gratitude for the amount of work which he has done in analysing his cases, and he is to be congratulated upon the good results of his practice.

LIBRARY TABLE.

The Illustrated Annual of Microscopy. London: Percy Lund, Humphries, and Co. 1898. Pp. 164. Price 2*s.* 6*d.* net.—The once familiar "Text-book" or "Complete Treatise on the Microscope," which included, beside an account of the instrument in its various forms, its history, accessories and method of use, a more or less complete description of, at least, samples taken from each of the three natural kingdoms, appears to be a thing of the past. This is, perhaps, hardly a matter for surprise, considering, first, the complete revolution which has taken place in the theory of microscopic vision during the past twenty years or so and, secondly, the intimate relation which the microscope now holds with nearly every department of physical science. These two factors have rendered it almost an impossibility to combine such an account of modern physical optics, including a discussion of the Abbe theory, as would suffice for more than an elementary student of physics, with anything but a most perfunctory description of the later methods of research and their application to biological science, as now understood, within the limits of a handbook. This may be seen from the last attempt of the kind—i.e., Dr. Dallinger's edition of "Carpenter on the Microscope," a work extending to close on 1100 octavo pages published in 1891. Here the first or optical portion has been entirely rewritten by the learned editor and associates and, as might have been expected, is thoroughly sound in theory and practice. The second or biological part, however, except such portions as bear on the editor's own researches and some few others where he called in the aid of specialists, remains very much as in the later editions issued in Dr. Carpenter's lifetime, when he had ceased to keep abreast with, or was too old to assimilate, more modern views. Hence this

Digitized by Google

latter is, for the most part, practically useless at the present time. Even if it be granted that such a work *might* be compiled by fortunate collaboration it would necessarily be cumbrous and, from the rapid advance of science, soon obsolete. Progress, then, can hardly be followed by the mere study of a text-book issued at rare intervals, and it is to the periodical that recourse must be had for the latest information. The "Illustrated Annual of Microscopy" is the newest attempt to supply the class it appeals to with up-to-date notions on the subjects it treats of. On the whole, and so far as it goes, we think it has succeeded; but the question may well arise whether such a limited survey of things microscopic as is presented in this first issue and its publication at yearly intervals will satisfy its readers. This, however, is a matter for its editor and publishers to settle and we are chiefly concerned with the contents of the Annual and the way in which they have been treated by the respective authors. The opening paper is on the Diphtheria Group of Bacilli, by Dr. J. Eyre, and the methods of demonstrating, cultivation, staining, &c., including the morphology of the various varieties, are well and clearly given. The process-block illustrations, however, leave something to be desired, as is usually the case, and they would, in our opinion, have shown to greater advantage on a black ground. Two articles on Photo-micrography are contributed, one by Mr. J. W. Gifford, who has rendered great services in this branch by his improvements in screens and light-filters, and another by a pseudonymous author who strongly advocates the use of magnesium ribbon as an illuminant. Mr. Gifford's paper, although short, is well worth the study of the beginner in this art. Dr. Henri Van Heurck, Director of the Antwerp Botanical Gardens, one of the best-known Continental microscopists, gives a review of the microscope in 1897 and such new apparatus as has been recently devised. Unfortunately, or the reverse, he finds "there is not one important invention to chronicle during this period, beyond the introduction of a few new models and the improvement of details in apparatus already existing." We have been for some time of the opinion that the present microscope with its objectives is already far beyond the capacity of the majority of its users. It is somewhat amusing to read Dr. Van Heurck's commendation of the objectives of a certain firm as excellent and sold at a reasonable price, one of which, a 1·5 mm. of 1·4 N.A., he says, *only* costs about £20. Mr. Rheinberg's article on Multiple Colour Illumination is probably one which will excite great interest in those who may not have seen his original papers in the Journal of the Royal Microscopical Society for 1896 or the Journal of the Quekett Microscopical Club for 1897. The method itself is not new, but Mr. Rheinberg was the first to reduce it to scientific exactitude, and its possible applications to certain problems of movement in living, transparent organisms make it of value beyond the merely charming manner in which it displays many familiar microscopic objects. The longest contribution to the Annual and one of paramount importance to the "brass and glass" microscopist is Mr. Conrad Beck's exposition of the theory of Gauss as applied to microscopic problems, entitled "The Elementary Theory of the Microscope." Gauss's formula has been explained and a worked example given in the Dallinger-Carpenter, but we do not think this system has ever been put forward with so great detail and with so much explanatory reasoning in any previous English work, and although we are far from saying that the path of the rays through the central portion of a system of lenses is, on this formula, made plain to the "meanest intelligence," it will undoubtedly be of great service to the amateur student of microscopic optics. Some knowledge of mathematics is, of course, necessary to the understanding of papers of this kind; neither does the Gaussian theory explain the whole of the problems involved in the optics of wide-angled objectives, but nevertheless it is a work to be welcomed and Mr. Beck deserves great credit for presenting it in the lucid manner in which he has done. Mr. M. I. Cross descants on "uniformity and accuracy," and deals, *inter alia*, with the urgent desirability of fixing upon some universal size or sizes for eye-pieces. We have some approximation to a universal gauge for objective threads, recently improved by the Royal Microscopical Society, but wide differences exist in the diameters of eye-pieces as supplied by the various opticians, English and Continental. He also treats of the dishonesty of some makers who, in many instances, wrongly state the focal length and aperture of their objectives. There are several other papers of interest to the amateur microscopist, but we are struck with astonishment at the admission of one query in the body of the book—viz., "Living acari artificially produced. Is it a fact?" This rubbish, of course, refers to the *experiments* of the at one time notorious "philosopher" Crosse which are mentioned in "Vestiges of Creation." Such exploded nonsense is only fit for papers of the "Bits" order and we are left wondering how it obtained admission into a modern scientific work. Finally, and with this exception, we think the "Annual" a useful addition to the periodical literature of its class. It will no doubt be extended and made to embrace a somewhat wider range of subjects in future issues, but in its paper, typography, illustrations, and general freedom from error it is a distinct credit to its enterprising publishers.

Antiseptic Principles for Nurses. By C. E. RICHMOND, F.R.C.S. Eng., honorary surgeon, Ancoats Hospital, Manchester, &c. London: J. & A. Churchill. 1897. Pp. 47. Price 1*s.*—In this little book we find a short account of the reasons for precautions against sepsis expressed in language simple enough to engage the attention of the average nurse. Anything which will impress upon nurses the immense importance of every step taken in insuring asepsis is to be warmly welcomed, for a nurse is very apt to regard many of the procedures as unnecessary and, when opportunity offers, to relax her vigilance. In the last chapter the author has laid down the general rules which govern the surgeon in the dressing of wounds, but he has not gone further into the subject, considering that the nurse has every opportunity of acquiring a full knowledge of the practical application of these principles in the course of her duties in the wards.

Diseases of the Upper Respiratory Tract, the Nose, Pharynx, and Larynx. By P. WATSON WILLIAMS, M.D. Lond., physician to out-patients and in charge of the Throat Department at the Bristol Royal Infirmary, &c. Third edition. 1898. Bristol: John Wright and Co. 8vo. Pp. 282. Price 8*s.* 6*d.*—When noticing in 1894 the first edition of this work we were able to praise the clearness of the account which it gives of the diseases of a very important part of the body. We do not know of any volume of its size which we would rather recommend to those students and practitioners who wish to have a fuller account of the medicine and surgery of the nose and throat than is to be found in the ordinary text-books. The illustrations are numerous and good; there are five coloured plates showing the normal and abnormal appearances of the larynx, pharynx, and nose. A useful table is given on page 70; it summarises the main points of distinction between some of the most common diseases of the tonsil. Though the differences between the present edition and the first are not very great, yet the whole book has been revised and brought up to date.

BRISTOL CHILDREN'S HOSPITAL.—A well-equipped laundry has been recently added to the Bristol Children's Hospital. The cost, for which the ordinary income of the institution will not be used, is about £1200.

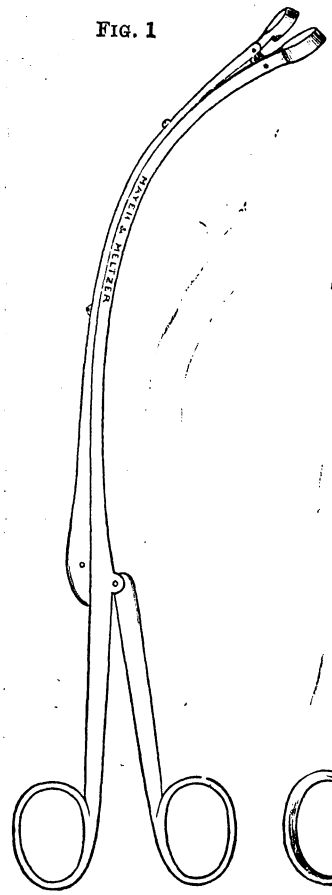
New Inventions.

CUTTING FORCEPS FOR USE IN THE TREATMENT OF LARYNGEAL PHTHISIS.

THE forceps depicted in Fig. 1 were shown at the Laryngological Society of London during 1898. Fig. 3 is a sketch of the cutting end, the circle being the exact size of a piece of paper cut out by the instrument. Figs. 2 and 4 represent an

FIG. 1



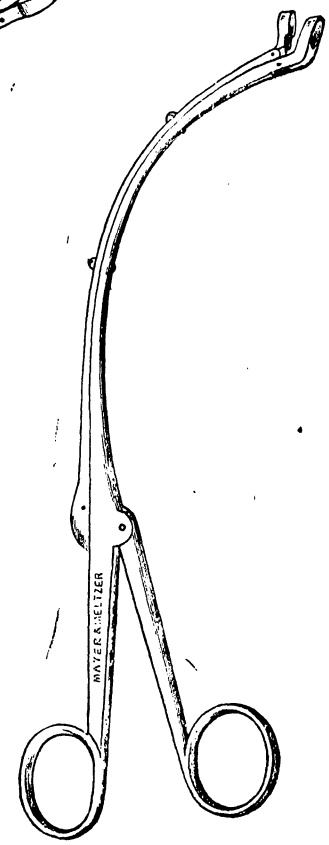


FIG. 2.

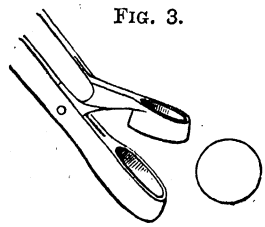
instrument which is made for removing superabundant tissue from the inter-arytenoid region, with a drawing of the and and of the sized piece capable of removal; both the letter full size. These forceps are of strong build and will cut through dense tissue or cartilage with the greatest ease.

FIG. 3.



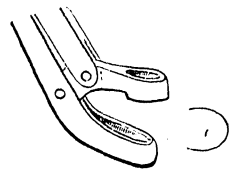


FIG. 4.

This is a point of considerable practical importance in laryngeal surgery and one often has to regret the weakness of tube forceps in punching out pieces of the glottic rima. The anterior-posterior cutting forceps will be found useful in removing tissue from practically every part of the rima, including the epiglottis, and no tissue will be found too dense. The downward cutting ones are for removal of those warty intra-arytenoid masses so hard to remove with any other instrument. They cut a little obliquely to suit the normal slope of the inter-arytenoid fold. These instruments are made by Messrs. Mayer and Meltzer, of 71, Great Portland-street.

Harley-street, W. RICHARD LAKE, F.R.C.S. Eng.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Oct. 13th, the President, Sir WILLIAM MAC CORMAC, Bart., K.C.V.O., being in the chair.

It was decided to place the bust of Sir Richard Owen, by Mr. Alfred Gilbert, R.A., in the entrance hall of the Museum.

The Council adopted the following recommendations of the Committee of Management:—

1. That Hymers College, Hull, be added to the list of institutions recognised for instruction in chemistry, physics, practical chemistry, and biology; and that Reading School be added to the list for instruction in chemistry, physics, and practical chemistry.
2. That the University of Yale and the University of Malta be added to the list of institutions recognised by the Board at which the whole curriculum of professional study may be completed and whose graduates in medicine are admissible to the Final Examination.

The Committee of Management further reported that they had granted permission for the meeting of the International Otological Congress to be held at the Examination Hall in August, 1899.

Sir William Mac Cormac, who had retired by rotation from the Committee of Management, was re-elected.

The Laboratories Committee presented the following report, which was adopted:—

1. *The work on diphtheria for the Metropolitan Asylums Board. Preparation of antitoxin.*—Since June 3rd 7050 doses of antitoxin, each containing 2000 units, and 2325 doses each containing 4000 units, for the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board, have been supplied and all the demands fully met. During this period 23,400,000 units have been supplied. Taking the quarter from June 3rd to Sept. 1st the figures are: 6300 doses of 2000 units and 600 of 4000 units, or 15,000,000 units in all, against 12,000,000 for the previous quarter. During this period the average strength of the antitoxin has been still further raised, so that it has been possible to send out 2000 units in quantities of from 4·25 to 5 c.c.
2. *Researches in connexion with the grant from the Goldsmiths' Company.* — Dr. T. G. Brodie and Dr. Cartwright Wood have continued their investigations and have planned out further series of experiments for the coming winter. The committee have unanimously awarded to each of them a further sum of £50 from the Research Grant as a recognition of their valuable work. The demand for antitoxin supplies to general and children's hospitals in London, in accordance with the conditions of the grant from the Goldsmiths' Company, for use among the poorer classes of the community is steadily increasing; 730 doses, containing in all 1,500,000 units, have been applied for and sent out during the past four months.
3. The Committee also report to the two Colleges that the director has forwarded to the Royal College of Physicians an account of an investigation carried on on the arrow poison received by the College from the Foreign Office.

Mr. H. G. Howse was re-elected a member of the Laboratories' Committee.

The Council appointed Mr. William Hardy Fleetwood, late of Epsom College, and now a student of the London Hospital, as the sixth Jenks scholar.

Mr. MORRIS, as chairman of the Annual Report Committee, submitted for the consideration of the Council a draft copy of the report to be presented to the Fellows and Members at the annual meeting to be held on Nov. 17th, 1898. It was approved.

The attention of the Council having been called by a local branch of the Incorporated Medical Practitioners' Association to the connexion of a Member of the College with a friendly society, it was determined that the branch of the association should be informed that the Council expressed their disapproval of canvassing for patients and of the employment of professional advertisements addressed directly to the lay public, and that this opinion would be communicated to the Member in question. It was also determined that the branch of the association should be informed that, as it did not appear to the Council that the society in question differed in any essential particulars from other registered friendly societies, the Council could not take any action in the case.

The SECRETARY reported that he had received the copy by Mr. John L. Reilly of the portrait by Mr. Stephen Pearce of Sir Erasmus Wilson, which was offered to the Council at the beginning of this year, and that the donor was Mr. Arthur H. Heywood, of Elleray, Windermere.

The Council voted their best thanks to Mr. Heywood for his present.

The PRESIDENT stated that the Bradshaw Lecture would be delivered by Mr. T. Pickering Pick on Wednesday, Dec. 7th, at 5 o'clock P.M., and that the subject of the lecture would be "The Union of Wounds."

A letter was read from Mr. T. M. Hocken, M.R.C.S. Eng., of Dunedin, New Zealand, asking the Council to consider the advisability of instituting a gown for the Members of the College. The subject was referred to a committee.

THE LANCET.

LONDON: SATURDAY, OCTOBER 22, 1898.

IT is simply a platitude to say that the continuance of plague in India is a most serious matter and one which places the Government of that country in an extremely difficult position between the opposing forces of sanitation and political expediency. While attempts are being made to limit its spread by restrictive measures disaffection has been growing apace among the natives owing to their strong opposition to the measures which have been hitherto taken to suppress the disease. It is, of course, impossible to stamp out a disease like plague without much irritating interference with the liberty of the subject, by entering their houses and by obtruding into their domestic life in many ways very objectionable to Easterns. And so it has come about that, whether Hindu or Mahomedan, the natives are far less terrified at the risk of contracting plague than at the measures taken to suppress it. Moreover, if the attempt at stamping out an infectious disease is to be efficacious as a precautionary proceeding, its limits of application in point of numbers, time, and space must be regarded. Preventive measures must be rigidly enforced from the very beginning of an outbreak and whilst it is still circumscribed within narrow bounds and while the numbers attacked are still relatively small. Failure within a given time to suppress what threatens to become an invading epidemic by any stamping-out process may be taken as indicating that further efforts in this direction will prove futile. We must in that case fall back for hope of success on the general sanitary conditions being such that the disease cannot obtain any secure foothold for its continued existence.

To quote the words of the Indian Government, "To attempt by force to eradicate a disease when the entire population exerts itself to oppose the methods adopted is an effort foredoomed to failure." It must be borne in mind, too, that, as far as Western nations are concerned, the knowledge of plague until quite recently was extremely small and of a literary and academic, rather than of any practical or scientific, kind. The measures which have been taken in India have, we regret to say, been only partially successful, with the exception perhaps of M. HAFFKINE'S system of inoculation, about which, however, we do not yet know enough to decide positively whether it is efficacious and, if so, how long the immunity conferred by it lasts, or whether it is a practicable scheme to apply in India with its teeming population. The present epidemic of plague made its first appearance at Bombay in the autumn of 1896 and it is still there. It has shown itself in greatest intensity and persistency in Western India, but it has nevertheless become widely spread over India generally. It is difficult to say which is the worst feature connected with it—whether the sickness and grave mortality it has caused, or the financial loss, commercial distress, and popular opposition and disaffection that it has entailed. The deaths from plague have not, after all, been so numerous as in a severe and widespread epidemic of cholera or as in the chronic drain on life attributable to the malarial fevers of India and their consequences. The Government of India, to do it justice, usually has the courage of its opinions in such matters, but it cannot go on indefinitely spending money and incurring the almost certain risk of a widely spreading disaffection among its subject races without having strong grounds for its action. We think, therefore, now that bubonic plague may be almost regarded as endemic in Bombay and Western India, that the Government is right to amend and relax the stringency of the measures it has adopted hitherto. During the three years in which plague has existed in India we have had time to discount the danger of its importation into Europe, and, as Major J. CRIMMIN, V.C., of the Indian Medical Service, has very pertinently pointed out, there are places in the Persian Gulf and Red Sea nearer Europe where plague has been endemic for some years past.

Recent bacteriological researches have revealed to us the intimate relations of plague to a bacillus, which, whilst vegetating and proliferating in the lymphatic glands, probably elaborates the virulent poison or toxin which acts so fatally on the tissues of the circulatory and nervous systems. Sometimes the plague bacillus or its virus passes into the general system without the intervention of such glandular manifestations, but the striking and common feature of plague is that it is bubonic. Now, accepting the pathological correctness of this view, there still remains a great deal to be cleared up about the history of this micro-organism and its vehicles, how it gains an entrance into the human body, the way to prevent its doing so, how it manifests its presence, and how to render the system immune to its morbid action. The relations of this bacillus to the lower forms of animal life, too, have to be more exactly determined, as well as its relation to insanitary conditions generally and to those of defective domestic hygiene. We are very glad, therefore, to see that the Government is appointing a Special Commission for the purpose of making scientific inquiry into plague and of investigating the origin of the various outbreaks, the manner in which the disease is spread, and the effects of curative serum and preventive inoculation.

IT will be universally admitted that in free countries legislation should be as much as possible in accordance with the general sense and intelligence of the people. Many a great law-giver from the time of MOSES has had to wait before he promulgated what he knew to be the right law because the people for whom he was legislating were not ready to receive it. The same difficulty occurs to all legislators, especially in free and democratic countries. The working of this principle affects for the worse every question which has to be dealt with by statesmen, but the results are most serious or even pernicious when they arise with regard to questions more or less technical and special. Faddism is well recognised by men of all parties and by universal consent certain questions

Digitized by Google

are to be raised above all petty and party considerations. There are many men in every party who feel that to deal with these questions from a party point of view is to degrade and dishonour Parliament itself. Among such subjects the health of the people is pre-eminently the first. There are wire-pullers and opportunists in all parties who would be prepared to make party capital even out of such a subject. But we are loth to believe that there is not a sufficient number of sensible and humane men in every party who would if rightly guided secure the settlement of such questions on non-party lines and in a way consistent with the judgment of those who, after all, are responsible for the health of the people, whether in the way of safeguarding it or of restoring it when it has been lost. It is obvious that a system of State Medicine can only be formulated by those who are familiar with disease, and that only those who have studied the causes of disease can be competent to advise as to the means by which such causes can be counteracted. There are diseases which prevail on so large a scale and so grievously affect the happiness of the people as to be suitable subjects for State action. Such are the great groups of infectious disease, including tuberculosis.

Two recent events show how erroneously some sections of society conceive of the duties of the State in respect of public health. When diphtheria-antitoxin was first introduced in the Metropolitan Asylums Board hospitals a group of gentlemen waited, if we remember rightly, on the President of the Local Government Board to protest against such a therapeutic measure being used in rate-supported establishments. They did not propose themselves to treat the children dying from diphtheria in these institutions, but they deliberately desired to tie the hands of the medical officers who had studied the subject and were responsible for the life of these children by withholding the one remedy which has been found more efficacious than all others. The very audacity of the proposal defeated itself. Diphtheria is now to some extent a controllable disease so long as it is treated according to the teachings of medical science, and many of the sanitary authorities are displaying a commendable readiness to adopt the latest suggestions of science for the detection and treatment of it. Is it not remarkable that a body of totally uninformed persons should take upon themselves to interrupt such work? The second event to which we have referred is the alteration of the Vaccination Acts in the direction of weakening the compulsory principle. This magnifies the liberty of the individual to incur the risk of contracting a disease which he may convey to twenty other persons before he is aware of having it—a precious result of liberty—but does not necessarily lead to an increase in the number of persons refusing to be vaccinated. All medical opinion is solid in regarding vaccination and revaccination properly performed as a preventive of small-pox, but the position of the recalcitrants was such that strict compulsion was outside the realms of practical politics. This fact does not lessen the grave responsibility which ignorant persons have taken upon themselves in discrediting vaccination. Their action has led to the loss of many infant lives, a fact which cannot be gainsaid after a cursory examination of the incontrovertible figures.

Such instances of a want of harmony between scientific knowledge and popular judgment make it necessary to revert to the first principles of State Medicine and to ask what are the circumstances which justify the disregard of individual liberty or rather its subordination to the welfare of the public. The very conception of State Medicine implies that the State is to use all scientific hygienic safeguards and, if necessary, enforce them by compulsion. It is also implied that in so acting the State shall be guided by medical science, and by the best medical opinion it can command. "No one," says Mr. FROUDE, "talks of a right of private judgment in anything but religion; no one but a fool insists on his 'right to his own opinion' with his lawyer or his doctor. Able men who have given their time to special subjects are authorities upon these subjects to be listened to with deference, and the ultimate authority at any given time is the collective sense of the wisest men living in the department to which they belong." These sentences contain the fundamental principle of State Medicine. The State must take its medicine from the best medical opinion. If it act otherwise it will suffer, and in the long run will suffer on a huge scale. It follows that in matters concerning the health of the community the State should have no political divisions. It should act as a whole on the scientific opinion given to it.

IN London we are face to face with a very serious question—i.e., whether the present sources of the water-supply can be correctly considered as adequate for future needs. It is time that the question was cleared from political considerations and regarded by all as THE LANCET has been most resolute to regard it—in the calmer light of a problem which must soon be grappled with on grounds of absolute necessity. The question is beset with difficulties while it is one upon which "slashing" articles can easily be written, but readers of THE LANCET will be able to preserve an equal mind in considering it, as they, like us, are fortified by the exact knowledge concerning the various companies contained in our Special Commissioner's report. It must not be forgotten that considerable confidence in the present sources of supply was inspired by the deliberations of sundry Royal Commissions on the subject and notably the last Commission presided over by Lord BALFOUR of BURLEIGH. We now know that some conclusions contained in the report of this Commission do not coincide with the evidence of experience and were founded on errors of reckoning and judgment. The occurrence of drought has swept away very many of the most important points which the Commissioners thought proper to emphasise. More especially is this so in regard to the sufficiency of water for future requirements from the present sources of supply. Assurance was conveyed by many experts, including the water companies' engineers, that the Thames, the Lee, and the companies' wells could be relied upon for an abundant supply of pure water for forty years to come, a supply equal, under strained circumstances, to the needs of an increasing population even when calculated at a probably

Digitized by Google

over-estimated rate. Within five years of this pronouncement being made public the Lee has failed, the East London Water Company's reservoirs are empty, the flow of the Thames is seriously diminished, wells are dry and the New River Company is drawing upon every possible source, the whole of the circumstances carrying the conviction that the supply is approaching a dangerous limit. We have to think now not so much of the efficiency of the particular undertakings as of the adequacy and fitness of the present sources of supply.

It would seem on the face of it that the present sources must be supplemented and several schemes which have been urged in the past have now been revived by the scarcity of water which has prevailed in the East-end of London on three recent occasions. The construction of large reservoirs in the Thames and Lee valleys capable of holding the enormous excess of water coming down during times of flood is one proposal. The chief and most powerful objection to this is that such water is almost certain to be polluted, either because the efficient treatment of sewage discharged into the streams is seriously interfered with during flood times or because the storm water itself contains the washings of highly manured land or the overflow of cesspools. Again, it is said that the Cotswold Hills could be made to furnish a pure and abundant supply of water. This statement is at variance, however, with the findings of a committee of engineering experts who have thoroughly surveyed the suggested new water area. More recently it has been proposed to intercept the enormous volume of water running to waste from the London basin southwards into the sea beneath our south and south-east coasts. Finally, there is the scheme which has perhaps been more seriously taken into consideration than the rest, as presenting a more satisfactory solution of the problem—the bringing of water from Wales. It may be instructive in this last connexion to review the facts connected with the steps which have been taken and are being taken in some of the greatest and most populous towns in this country. We refer to Liverpool, Manchester, and Birmingham. Liverpool led the way in 1880 by commencing the construction of an enormou reservoir in the valley of the Vyrnwy in Wales and of a conduit which measured 77 miles in length from the Town Hall to the reservoir outlet. Lake Vyrnwy, as the reservoir is now called, is said to be the largest artificial sheet of water in the world and its capacity is 13,125,000,000 gallons. The water flows to Liverpool by gravitation and the total quantity available is 40,000,000 gallons per day after allowing an abundant overflow for compensation purposes to the river. The scheme has proved satisfactory, and Liverpool now we believe possesses a pure and adequate water service. The total cost of the scheme will be close upon £4,000,000. In 1885 operations were commenced by the Manchester Corporation with the view of making the water of Lake Thirlmere, in Cumberland, available for the city of Manchester. The distance in this case is 96 miles. At present 10,000,000 gallons are delivered in Manchester per day, but this will shortly be increased, by adding more pipes, to 50,000,000 gallons per day. The total cost is thus estimated at between £4,000,000 and £5,000,000. Finally, the scheme of water-supply to Birmingham is proceeding at the present time and it is hoped that it will be completed in ten years.[1] In this case the watershed of the rivers Elan and Claerwen in mid-Wales was decided upon. The works were commenced by the construction of a railway in 1894 and the ceremony of the laying of the commemoration stone of the reservoir took place in May, 1897. Since that date the task of collecting the supply and bringing it 80 miles across country, through mountains and over valleys, has proceeded apace, with what final success remains to be seen. The estimated cost of the scheme, including the purchase of the watershed, was £6,500,000, but we believe that this will be exceeded, if it has not been so already. The supply will provide, it is said, for a period of fifty years in advance, and for this it is calculated that 60,000,000 gallons a day will be the maximum supply which Birmingham will then require in dry weather. With these schemes, accomplished and proceeding, it is of interest to turn to the plans placed by Sir A. BINNIE before the London County Council, by which it is proposed to acquire a watershed in Wales for the London supply, not in substitution of but rather to supplement the existing sources. Sir A. BINNIE looks to the valley of the Irvon, a tributary of the Wye, as the best available for the purpose. The shortest aqueduct to London would be 150 miles long. The cost of bringing the water from Wales to supplement the Thames supply would, it is stated, be £14,000,000, and to provide for a future period of fifty years the extra cost would be £12,000,000, making £26,000,000 in all.

It would be obviously premature to express adhesion to any new proposal without obtaining a full and comprehensive knowledge of all the factors concerned. That the question is, as we have said, beset with difficulties is evident from the fact that it is once more being approached by a Royal Commission, an account of whose sittings up to the present date we have published at some length. The President of the Local Government Board has promised to draw the attention of the chairman of this Commission, Lord LLANDAFF, to the recent failure of the supply in the East-end of London, when we shall be curious to see how the events of this summer are treated by the Commissioners. That the extent and mischief of the water famine have been exaggerated by some does not alter the fact that a serious breakdown occurred and it is quite possible that the Commission will attach much importance to it, even if it does not shape the ultimate report.

UNDER the heading of "The Ethics of Club Practice" we published last week a letter setting forth some of the difficulties of this kind of medical work and showing how easily the most careful practitioner may find himself blamed for that which he cannot help. The facts were as follows: The writer of the letter, a surgeon who had served his society without complaint for thirty years, was called on a Monday morning to attend one of the members who was

[1] An excellent and entertaining account of the progress of the works in connexion with the Birmingham scheme will be found in a book recently published under the title of "The Future Water-supply of Birmingham," by Thomas Barclay. London: Simpkin, Marshall, and Co. 1898.

Digitized by Google

suffering from quinsy. He saw him on that morning and promised to see him again on the following morning. When the Tuesday came there was an unforeseen pressure of duties and he could not see his patient at the time appointed. But he sent his qualified assistant, and the interval between the visits was, according to the patient himself, only twenty-six hours. When the assistant called he learned that the patient had called in another medical man living nearer. The quinsy soon disappeared, but obscure brain symptoms, apparently connected with a previous blow on the head came on. The patient was removed to a hospital to be watched with a view to operation. But the symptoms happily passed off. A few weeks later he wrote to the secretary of the society complaining in very strong language of having been neglected by the medical officer of the society and demanding from the latter payment of the bill of the second practitioner called in. Our correspondent refused to pay the bill on the ground that he was under no contract to see the patient at any given hour and that on any given day a medical man must himself be the judge of the urgency of cases and the order in which they should be seen. The second practitioner called in telephoned to the first as to the case and the latter assented to his taking charge of it. The facts seem very simple. Of course, we are writing on a statement of the case by the person inculpated. But the essential points seem to be admitted by the patient and we have no hesitation in expressing our opinion on them. Our correspondent seems chiefly anxious to know whether he can be compelled to pay the account incurred by the patient in calling a private practitioner to attend him. That is a legal question on which we pretend to speak with no special authority. We have no doubt that the surgeon of a society, under contract to attend its members and grossly failing to do so, would be liable in any reasonable amount for expenses incurred by his neglect. But whether in this individual case any such liability would be recognised we should think a matter of great doubt. An interval of twenty-six hours between visits in a case of quinsy is not an unreasonable one, and to say that a medical man fails in his duty because under stress of work he sends a fully qualified assistant in his stead is to advance a very questionable proposition and one which, we think, a county-court judge would be slow to endorse. No medical man can forecast one day what will be the nature of his duties the next, what will be the number of his cases, and what the respective urgency of each. No doubt an excitable man with quinsy would think his case bad enough, but the medical man might have a midwifery case or an accident, or a case of pneumonia, or a combination of such cases claiming his prior attention. Of this he must be the judge. Our correspondent's argument on the matter seems to us unanswerable, and it is strengthened by the letter which he publishes from the medical man who succeeded him in the charge of the case. This gentleman says that when he was called in the quinsy was actually on the decline and the secondary disease which supervened, and which was really the graver of the two, had not yet declared itself. The patient, who considered himself so badly used, "treated in a way not fit for any human being," may be comforted by knowing that what happened to him happens every day to the patients of private practitioners; for medical men have to take their rounds in a certain order, the order being determined chiefly by the comparative urgency of cases. We cannot think that on further reflection the patient in this case will think that he has treated the surgeon of his society with due consideration. Every practitioner requires, and is entitled to, some allowance at the hands of his patients, so impossible is it for him to prearrange his day exactly. Not only is he entitled to it, but in nine hundred and ninety-nine cases out of a thousand he receives it. Still more is the surgeon of a society entitled to it, because he is presumably attending a larger number of persons than a private practitioner and that for less remuneration, and especially when, as in this instance, his term of office has extended over thirty years and his work has secured for him the friendship and confidence of the members. Such a record is creditable to any medical man and to the society which he serves. It should almost suffice of itself to refute any charge of culpable neglect and certainly would appeal powerfully to any judge to whom the facts of the case might be referred.

Annotations.

"Ne quid nimis."

THE WORK OF THE GOVERNMENT LABORATORY.

WE believe that hitherto it was not the practice to issue a blue-book on the annual work of the Government Laboratory, the new departure apparently being commenced soon after Dr. Thorpe was appointed as principal two years ago. This would explain why two blue-books have been issued at the same time, one dealing with the work of the year ending March, 1897, and the other with the year ending March, 1898. The fact of the report of the work done being published in this official manner for the first time is alluded to incidentally in the 1897 report, where an explanation is offered of certain returns, "as this is the first report made direct to your lordships." We are surprised that this course has not been adopted before, since the important relation of this department to trade and commerce besides public administration is obvious. And, as we expected, the first blue-book contains some very interesting particulars. The work of the Inland Revenue branch of the Government Laboratory had its origin in controlling the strength of alcoholic liquors and other dutiable commodities. In short, its main object was to afford assistance to the Excise department and thus to secure the proper amount of Inland Revenue due on certain taxed goods. The work has now developed enormously, so that the chemical authorities are now consulted by the Government Offices in regard to the analysis of many trade products. At the present time samples are sent to the Government Laboratory by almost all the official departments of the Government Offices. During the official year 1897 the number of samples so referred amounted to a total of 2990. Amongst these were articles of food, drugs, disinfectants, oils, paints, fertilisers, &c. Under the Sale of Food and Drugs Act 65 samples were referred to the Government analysts as being cases under dispute. Of these 42 consisted of milk. On the whole, considering the number of samples examined annually by the public analysts in the United Kingdom, the result of reference is a tribute to the excellence and exactness of their work.

Digitized by Google

The 1897 report draws attention to a point which we have frequently raised in our columns. The Government Laboratory authorities had a number of proprietary disinfectants submitted to them, chiefly by the Board of Trade and the India Office, for the determination of their antiseptic and disinfectant properties. It is remarked that there is a growing tendency to offer as disinfectants various indefinite mixtures of tar products, containing small proportions of carbolic and cresylic acids, but chiefly consisting of neutral bodies of little or no antiseptic value. We thoroughly agree with the observation that the varying composition and antiseptic power of these preparations, which, as a rule, are waste products, offered at a low price, render their use as a class inadvisable and compel a resort to the much longer method of biological examination as a test of antiseptic efficiency instead of the briefer chemical analysis. In view of the importance of this subject we might have anticipated that the Government Laboratory authorities would have made some provision for examining the so-called disinfectant preparations on the lines indicated, but we find no further reference to the subject in the succeeding report of 1898. There is little doubt that the Government enter into large contracts for a supply of disinfectants at home and abroad, and the Government department should be able to declare the real efficiency or worthlessness of these preparations. The new Government Laboratories were completed in October, 1897, the premises being situated in Carey-street, near the Law Courts, so that there are now no chemists at Somerset House and the familiar term "Somerset House referees" must in future be omitted. Considerable work has been done during the past official year with beer in order to effect a more satisfactory control over the dilution of beer with water. 14 per cent. of the samples examined were found to have been diluted and in one case the dilution was equivalent to 10·9 gallons of water in the barrel of 36 gallons. The practice by retailers of diluting beer appears to have been confined to London. Tobacco does not appear to be free from unscrupulous tricks, for of 60 samples taken 35 were found to be genuine and 25 adulterated. This probably refers to excessive moisture and mineral matter. The department, we venture to suggest, might turn its attention to the question of foreign flavouring substances in tobacco. As in previous years, the samples referred to the Government Laboratory as cases in dispute consisted largely of milk. Of 39 samples of this class 29 cases were upheld. The only serious differences occurring at all under this section were connected with samples of lard and spirits. On the whole, however, the 1898 report affords once more a testimonial to the skill and efficiency of the work done by public analysts. According to the recommendations of a Select Committee which will be embodied in a Bill to be introduced to the House of Commons next Session the relations existing between the Government analysts as referees and the public analysts at large should be still more satisfactory, so that probably a greater proportion of the cases under dispute will be officially confirmed by the chemists of the new Government Laboratory.

THE MEDICAL PROFESSION AND MASSAGE ESTABLISHMENTS.

AT length the proprietor of a massage house has been laid by the heels and sentenced to six months' imprisonment with hard labour for assault and, under the new Vagrancy Act, to three months' imprisonment with hard labour for "knowingly living wholly or in part on the earnings of prostitution." The name of this blackguard is James Davis and he lived at 120, Marylebone-road. We are not so much concerned with the immorality of his proceedings, but we might mention that we fail to see why hardworking taxpayers should support a person of this description for nine months, feed him and keep a roof over his head. A sound flogging every other day for a week would be much cheaper and would hurt a good deal more. However, that is not the point with which we wish to deal. The house in question nominally existed as an establishment where definite medical treatment — i.e., massage—was given. It was called the "Balneopathic Institute for the Treatment of Rheumatism, Gout, Sciatica, and Neuralgia by Dry Hot-air Baths, Massage, &c." As a matter of fact, it was nothing more or less than a brothel. Now, brothels have existed in large towns from the time of ancient Babylon downwards and we suppose they always will exist. With that we have nothing to do. But, as we said on a former occasion[1] when commenting upon massage establishments, such houses should not be allowed to masquerade under the name of places for legitimate medical treatment. A woman who gave evidence as one who attended when the house was short of "nurses" said that she knew nothing about massage but that she gave treatment with the birch. Gentlemen who underwent this treatment used to be known to our ancestors by the name of "flogging cullies," and further details need not be gone into. We can only hope that the remaining houses of this description—and there are plenty of them in other parishes than St. Marylebone—will be suppressed in as vigorous a manner.

THE ROYAL MEDICAL BENEVOLENT COLLEGE

THAT there is a turning point in the fortunes of most men is a recognised truism and that this also applies to many institutions has been proved over and over again. In another column we publish an appeal on behalf of the Royal Medical Benevolent College at Epsom, from which it would appear that after doing a steadily increasing amount of good work for more than forty years the institution has at last arrived at the road leading to well-deserved prosperity; but whether this desired goal is to be eventually reached depends, we feel quite sure, upon the extent of the support given now and in the future by the rank and file of the profession. The appeal puts the matter in a nutshell when it states: "If each member of the profession would give 10*s*. or even 5*s*. a year for a very few years the position of the pensioners and foundation scholars would be placed on a secure financial basis and the Council would be able to improve the school and extend its usefulness still more." Though substantial help from comparatively a few leading practitioners must be very welcome it may be safely asserted that the permanent success of the College can best be secured by the small contributions of many thousands of supporters. We would observe for the information of those not well acquainted with the work carried on by this important institution that there are two distinct branches—namely, charitable and educational. On the benevolent side 50 pensioners receive annuities and 50 foundation scholars are boarded, clothed, educated, and maintained, the total liabilities of this branch exceeding £6000 per annum. On the scholastic side a thoroughly sound public school training is given to the sons of medical men and others, the fees charged to members of the profession being considerably reduced, and in addition valuable exhibitions and scholarships are offered. It should be noted that these observations refer only to the work actually done by the College out of its general funds and not to the special annuities, scholarships, and exhibitions provided by generous benefactors. An important period in the history of the College was the year 1895, when the maximum amount of good that could possibly be accomplished was being carried out on both sides of the institution. The school was in a

[1] THE LANCET, Feb. 20th, 1897, p. 538.

Digitized by Google

flourishing condition and for some time had been quite full, so that the Council decided after mature consideration to extend the accommodation by building a lower or junior school and at the same time to enlarge the chapel and build a laundry, works which have all been completed. As to the charity, that had for several years been maintaining the full number of pensioners and foundation scholars, and, owing to a munificent legacy from a Melbourne practitioner, the annuities of all non-resident pensioners had been raised from £21 to £30 per annum. As some of our readers will recall to mind, the increase in the amount of the non-resident pensions was a matter in which for years we took a deep interest; in fact, in 1892 we had the pleasure of handing the sum of £1000 to the treasurer, Dr. Holman, who was the originator of the movement, to be the nucleus of a fund to provide increased annuities for those who preferred to live away from the asylum. We were unable to shut our eyes to the fact that it was not a kindness to take aged ladies and gentlemen away from old beloved associations to end their days amongst strangers; and, moreover, it hardly seemed to be a judicious course to train boys for a medical life with the few sad failures of the profession constantly before their eyes. It may be asked, How can medical men help on the good work of the College? There are several ways. First, by contributing an annual subscription of any amount from 5*s*. upwards; secondly, by procuring contributions from the public, who are under a debt of obligation to the profession; thirdly, by sending their own sons to the College, where they will receive a first-class education at a moderate charge; and, lastly, by drawing the attention of those outside the profession to the many educational advantages offered at Epsom. That the school has for one of its size a thorough good record to show in successes gained at the universities and at the medical schools in London we can assure our readers, and the authorities at the College will no doubt willingly give to applicants detailed information as to honours gained in past years. In thus supplementing the appeal of the Council for increased support, which we have much pleasure in doing, it will be interesting to recall to mind an observation made by us long before the College was actually incorporated. In THE LANCET of May 3rd, 1851, we wrote—and it is hardly necessary to state that the observation still accurately expresses our views: "For the objects of the institution whether for eleemosynary or educational purposes we have but one word and one thought—that of hearty coöperation and support."

MIDWIVES AND THE DEATHS OF CHILDREN.

THE death of Joseph Sartori, three days old, at Windsor, has been the subject of a coroner's inquest. The mother was attended by a certified midwife, Mrs. Taylor. Mrs. Taylor had attended her in two previous confinements. On this occasion she was with the patient for seven hours, and an hour before the birth she administered a dose of ergot which, she said, had been her custom in the circumstances for twenty-six years without bad effects. On the day of the birth, a Tuesday, the infant passed blood with the urine. The next day the midwife did not call but sent her daughter. The daughter was asked to tell her mother of the blood in the urine. On Thursday Mrs. Taylor called. There was no mistake about hæmaturia and she advised that if the child was not better the next day a medical man should be sent for. Next day she came and finding the child very ill she took it well wrapped up to Mr. W. L. Goodridge, who found it moribund. In spite of the measures prescribed the child died on the way home. The coroner did not order a post-mortem examination, which we regret, but Mr. Goodridge saw the body after death. There was great abdominal distension, and a catheter passed into the bladder showed it to be empty. He attributed death to inflammation of the kidney. At the inquest he expressed his own opinion and that of the profession on the objections to giving ergot during labour, and especially to midwives being allowed to do so. He said that a Bill to be introduced into Parliament next year would make this a matter of criminal procedure. He thought that there was no evidence to show neglect at birth and that there was no mark of violence. The jury returned a verdict of "Death from natural causes." We approve the verdict but the case shows the importance of midwives' work being supervised by a medical man. For three days hæmaturia and probably nephritis were going on. If Mr. Goodridge had been called in on the first day when it was seen it is very probable the result might have been different. The coroner very properly objected to such young children being taken out, especially in such circumstances. The cause of the hæmaturia is uncertain and its relation to an alleged fall of the mother during her pregnancy is equally so. We do not associate it with the drug administered to the mother by the midwife, though we agree entirely with Mr. Goodridge in his objection to this practice. The inquest is valuable as showing the ignorance of midwives in this custom and the general disadvantage of mother and child in the absence of intelligent medical advice.

RESTORATION OF SEVERED PARTS.

THE possibility of restoring severed parts, even under unfavourable circumstances, is not so generally appreciated as it should be, and attempts which might be successful are not made. Lately we published three cases in which the severed external ear was successfully replaced.[1] In one (Dr. Brown's) the circumstances were anything but encouraging. The ear had been bitten off by a horse and was found lying in a stable yard. Neither surgical instruments nor antiseptics were available: a common needle and thread had to be used. In the other two cases (Dr. Purcell's) the surgeon adopted the ingenious plan of keeping the ear warm and endeavouring to restore the circulation by hot salt bags. We do not know of any other instances in the attempt to restore severed parts in which this had been done. To what extent it is useful is difficult to say; at any rate, it is rational. Several cases of union of severed finger tips are recorded. In the *Johns Hopkins' Bulletin*, Oct.–Nov., 1892, Dr. Finney has published a case of successful suture of severed finger-tips after seven hours. The middle finger was cut off just below the last joint through the phalanx, the ring finger at the root of the nail. The raw surfaces were freshened and the tips were attached each by four sutures. Dr. Finney used antiseptic dressings but not solutions, because bichloride of mercury and carbolic acid produce a thin layer of coagulation necrosis. The wounds united by first intention. In a recent number of the *New York Medical Journal* appears an account of the following case, published in the *Louisville Medical Monthly* by Dr. John Cooke Laurens. A coloured man in using a heavy axe cut through his shoe and severed the metatarsal bone of the first toe through the head, completely disarticulating the toe, and also cut off the second toe in front of the metatarsal joint. He was seen four hours afterwards. The shoe and sock were cut away and the second toe was found separated, whilst the first was hanging by a mere string of skin, every muscle and vessel being cut. They were united by interrupted sutures which included the tendons. A dressing of iodoform and boric acid, equal parts, was used and a splint was applied. The iodoform had to be discontinued because it proved

[1] THE LANCET, June 4th and 11th, 1898.

Digitized by Google

irritating. Union by first intention occurred over more than half the wound and there was but little pus where granulation took place. On the third day sensibility was present in both toes and in a week the patient could move them a little. Finally they were strong, moveable, and sensible, and except for a little tenderness the foot was as good as ever.

THE DINNER TO PROFESSOR VIRCHOW.

DR. ROSE BRADFORD, Mr. Andrew Clark, and Mr. D'Arcy Power inform us that after paying the expenses of the recent successful dinner given to Professor Virchow by the English medical profession there remained a balance of between £7 and £8. This sum they propose to hand over to the British Medical Benevolent Fund.

PERSECUTION FOR RETICENCE.

A LIBEL case has recently been decided by the Budapest courts which is of interest to medical men as showing the dangers to which the profession is exposed. A member of the Hungarian Parliament, who is both a barrister and the editor of a monthly journal, had a son who recently died from phthisis at the age of nineteen years, having been under the care of the family doctor for some time, several consultants having also seen him. After the lad's death the father published in his own magazine a series of articles charging the practitioner with ignorance and negligence, because he had for some time avoided declaring the "dangerous and infectious nature of the disease," and so contributed to its fatal issue and endangered the lives of other members of the family. These articles so affected the medical man that he committed suicide. His son, however, who is also a medical man, brought an action against the member of Parliament, who has had to pay £25 and costs.

THE POLLUTION OF THE RIVER RODING.

AT a time when the suggestion to utilise the upper reaches of the Roding for supplementing the supply of the East London Water Company to certain urban districts in the County of Essex is receiving serious attention, it is of interest to note that the County Council has decided to take prompt action in order to restrain a number of sanitary authorities from continuing to pollute it with partially purified sewage effluents. The river rises in a thinly populated portion of the county called the Roothings, but the whole watershed is under cultivation and the various tributaries are all believed to be more or less polluted with the sewage from farms and groups of houses. Lower down it receives all the sewage of Ongar, Abridge, and other villages, and still nearer its junction with the Thames it receives all the effluents from seven different sewage works. Below Abridge Dr. Thresh reported that the river was simply an open sewer. A committee appointed by the County Council has inspected the stream and endorses the medical officer's report, the chairman of the Sanitary Committee remarking at the recent meeting of the Council that the condition of the river was a "disgrace to civilisation." The Council delegated to the Sanitary Committee all its powers under the Rivers Pollution Act in order that proceedings may be taken, if necessary, "against each of the local authorities or persons who are fouling the stream with a view to the immediate abatement of the nuisance." Dr. Thresh in his report strongly recommends the construction of a main sewer to drain the whole of the Roding Valley, from Loughton downwards, as being at once the most economical and the only permanent method of freeing the river from pollution. The population in the lower portion of the valley is increasing enormously and all the present sewage-disposal works are admitted to be more or less inadequate. The scheme is meeting with very favourable consideration and if carried out will in the future be a great boon to the district. It is also gratifying to find that the County Council at the same meeting showed its appreciation of the services of its medical officer of health by increasing his salary from £800 to £1000 per annum.

HOSPITAL SATURDAY.

SATURDAY, Oct. 15th, was observed throughout the metropolis as Hospital Saturday and we are glad to be able to note that in deference to a very widely expressed desire the street collections were abandoned. Street collecting is a method to which we have always taken exception, and latterly it became impossible to walk along the streets at any season of the year or any hour of the day without being pestered for money ostensibly on behalf of some charity, which in many cases no doubt never existed except in the minds of some speculator who sent out collectors. The change now made by the committee of the Hospital Saturday Fund has been for some time in the air, since for many years past the street collections had been falling off while the workshop collections had been increasing. This year collecting cards and sheets have been issued to the ladies who formerly took part in the street collections and it is to be hoped that the ultimate results will not show a deficit at any rate, if, indeed, they do not show an increase upon the sum total of former years.

PNEUMONIA AND THE NAPLES INSTITUTE OF SEROTHERAPY.

OUR Rome Correspondent writes:—"Of the medical congresses now drawing to a close none have equalled in importance and interest that recently hel at Turin, if only for the discussion it evoked on the 'Siero Antipneumonico' devised by Professor De Renzi and Professor Pane of the Naples school and prepared by them for distribution at the 'Istituto Sieroterapico' of that city. Professor Pane, who holds the chair of Medical Pathology, was able to announce at the Congress that in a series of experiments on animals and by means of special cultures they had obtained a pneumococcus more virulent than any other hitherto found by workers in the same field. This given in doses of the culture so minute as to be barely appreciable (*un miliardesimo di c.c. della coltura*) kills a full-sized rabbit in a few hours. Inoculating the ass, the horse, and the cow with the culture in progressively increased quantities they yet succeeded in immunising the said quadrupeds from doses of the pneumococcus which would 'many times over' have proved fatal to any non-vaccinated animal. The serum of these animals they found to possess therapeutic virtues of special power in antagonising pneumonia. Before, however, experimenting on the human subject Professor Pane and his colleague and coadjutor, Professor De Renzi, tested their serum on the lower animals. Inoculating a rabbit with a culture of pneumococcus ten and even twenty times fatal they were able to 'antagonise the tendency to death' by following up the inoculation in question with a minute proportion of the serum. Repeated experiments, checked and counterchecked to obviate every vitiating fallacy, satisfied them that their serum had power to neutralise and subdue all infections, however acute and however fatal, communicable by the pneumococcus. In the hands of their colleagues, Dr. Vincenzo de Giaxa, professor of hygiene; Dr. Luciano Armanni, who holds the chair of pathological histology; and Dr. Giuseppe Boccardi, demonstrator in microscopic anatomy, identical results were obtained. Thereafter they proceeded to inject their serum in a patient suffering from typical pneumonia and at once witnessed a perceptible abatement of the temperature,

Digitized by Google

an easier and fuller respiration, a marked extension of the sound lung, the pulse and the arterial pressure being more accentuated, the heart gaining strength and the right ventricle completely emptying. The physiognomic signs told a similar tale and the patient felt such general relief as to crave for 'another injection.' In the discussion which followed Professor Pane's paper Professor Maragliano (Genoa), Professor Murri (Bologna), Professor Bozzolo (Turin), Professor Cantieri and Professor Bordoni (Siena), Professor Queirolo and Prosessor Silvestrini (Pisa), and many others hardly less distinguished took part, when the Neapolitan physicians, in answer to objections and interrogations, were able to adduce confirmatory cures by their serum of aggravated senile pneumonia, of pregnant women suffering from the same disease, and of patients with pneumonia complicated with various forms of cachexia. Among the most gratifying testimonies to its virtues was that of Dr. Belfanti, director of the Istituto Sieroterapico of Milan, who confessed that he had not been able to isolate a pneumococcus so virulent as that of Professor Pane and Professor De Renzi. He had just succeeded in preparing a bactericidal and preventive serum, but not a curative one or such as would prove effective in cases of pneumonia. Professor Bozzolo added his own experience to that of the able Milanese bacteriologist, and contributed to justify the expectation of the Congress that pneumonia will ere long cease to hold a formidable place in the roll of diseases."

YORK MEDICAL SOCIETY.

THE first meeting of the present session of the York Medical Society was held on Oct. 12th, the President, Mr. F. Shann, being in the chair. Dr. Lauder Brunton delivered an inaugural address on the subject of "Exercise and Over-exercise" which contained much excellent advice on the value of judiciously regulated exercise. Certain points in this interesting address are more particularly noteworthy. The sanitary value of physical exertion, the speaker observed, consists largely in the fact that it calls into play successively different muscles, affording to each alternate rest and action. This was what constituted the advantage possessed by an athletic game over a mere "constitutional." Some games, again, were preferable for the same reason. Lawn tennis and polo were pre-eminent as promoting more general movement than most others, cricket not excepted. On the other hand, no caution was more necessary than that which avoids excess in exercise, for this, far from promoting physical development, was an actual cause of exhaustion and consequent enfeeblement. Moderation in exertion, as in other things, was a relative term dependent on personal conditions. Among such two were of primary importance: (1) the strength of the heart, which ought always to be taken as the gauge of what was advisable in amount of exercise; and (2) the mental state in relation either to fatigue or anxiety. Both of these considerations were apt to be overlooked in the training of boys (and doubtless of girls also). Every thinking person must feel the force of these observations. The subject they deal with can at no age become antiquated, and of this we are daily reminded by the evident extension of the athletic habit in varying, not always judiciously varying, degrees among persons of all ages. The custom of bodily exercise is in our time not merely a part of education or even a recreation. It owes its present practically universal prevalence to being what it truly is, an important stage in sanitary evolution. In order that it should maintain itself and develop in this character it will be needful to bear in mind such counsels as those which we have just quoted. If not thus regulated it must prove, as it already has proved to many even in youth, a burden and a weakness. We are glad to see that Dr. Brunton condemned that dreary form of exercise known as "taking a walk." Not that we or he either mean by this a good country walk, but the dignified constitutional known at small schools. If we may judge by such works as "Henry Milner" and the "Fairchild Family" this was about the only form of exercise known to our grandfathers when children, and a very dull and sedate occupation it must have been, though, if we remember rightly, the rigours of the Fairchild children's day were once lightened by being taken to see a murderer hanging in chains. Dr. Brunton omitted two forms of exercise which, to our mind, are excellent—namely, rowing and fives. The latter game should, of course, be played in an open court. The exigencies of our modern civilisation, however, make it increasingly difficult for workers, in London at any rate, to take exercise, for by the time their day's work is done they are generally too tired to go six or seven miles to a river, a lawn tennis court, or a golf links. But even so we as a nation probably take more healthful exercise than any other, and long may we continue to do so.

THE ADULTERATION OF FOOD ON SUNDAYS.

THERE is an old adage which has it that "the better the day the better the deed," but we hardly expect that those who practise the adulteration of food on Sunday and supply nothing but the genuine article on week-days will urge this as an excuse for their moral obliquity. Be this as it may, satisfaction is to be found in the fact that the public analyst of Islington has succeeded in catching some of these adulterators of our Sunday milk-supply unawares, and we read in the last quarterly report of Mr. Harris, the medical officer of health of Islington, that of 30 samples collected on week-days all were genuine, whereas out of 48 collected on Sunday 6·2 per cent. were adulterated. This is by no means the first record which suggests that the milk vendor believes that the sanitary inspector, like most of his fellow citizens, takes a well-earned rest on Sunday; but it is to be hoped that the experiences of Islington will show both to sanitary authorities and to the vendors of food stuffs the need for vigilance on that day. Perhaps if adulterators were in all cases fined double for adulterations actually performed on Sundays the public might feel in a more secure position than is at present the case.

MILITARY SANATORIA.

ACCORDING to a contemporary (the *Evening Standard* of Oct. 7th) the King of the Belgians, who is a remarkably astute and business-like monarch, has suggested a commendable idea for military sanatoria. The Congo State has occupied a good deal of his attention. One of the greatest drawbacks to the expansion of European rule in West Africa is the deadly climate and the difficulty of dealing satisfactorily with fever-stricken troops. If they remain at their posts they run every risk of succumbing; if they are brought back to northern Europe the sudden transition from a tropical temperature to the chills and damps of their own temperate countries may also prove disastrous. King Leopold, therefore, has in view the establishment of a sanatorium within reasonable touch of the Congo territories which shall be at once genial and free from malaria. North-Western Morocco was at first suggested, but a second and decidedly better scheme has presented itself and is in fair way of being carried through. The Canary Islands are considerably nearer the west coast than Morocco is and lie in the direct route of the Congo steamers. Their climatic conditions are too well known to medical men to need any remarks. A medical commission has left Antwerp for Las Palmas to choose the site for the sanatorium and the King has placed 25,000 francs at the head of the subscription list by which the necessary funds

Digitized by Google

are to be raised. It has always been the custom of our military medical service to provide hospital steamers for the reception of fever cases amongst our troops whenever large numbers have been on active service in malarial districts, but the establishment of a permanent sanatorium in a climate such as that of the Canaries, within easy reach of our West African dependencies, is certainly a plan well worthy of the consideration of the authorities of the Royal Army Medical Corps. English troops are constantly quartered in those districts and many valuable lives might be saved to our army by such an institution.

THE NEW ENTRIES AT THE MEDICAL SCHOOLS.

ALTHOUGH the London Medical Schools have now commenced the work of the winter session the number of new entries is not yet complete, but it would seem from the figures we have received from some of the schools that there has been a falling off in the number of new entries. At the present time it would be invidious to publish and compare the figures which have been kindly supplied to us by some of the deans and, moreover, from some of the schools we have not received exactly the information which we asked for. When the list is more complete we hope to publish a full analysis of the figures.

LIGATURE OF A RUPTURED MESENTERIC ARTERY.

ONE of the rarest lesions in a "buffer accident" is a rupture of a branch of one of the mesenteric arteries. Such an accident occurred recently to a railway porter and he was admitted in a state of collapse into the Royal Free Hospital. As the collapse seemed to diminish, operation was temporarily postponed, but later, as it was again increasing, it was decided to operate. Mr. E. W. Roughton opened the abdomen and found that one of the vasa intestini tenuis had been torn through about 1 in. from its origin. The distal end was bleeding freely and both ends were tied. The peritoneal cavity contained much blood and the collapse was so extreme that saline transfusion was resorted to during the operation. The man has so far gone on well, and as ten days have now elapsed since the operation he will in all probability recover. We hope shortly to give a more detailed account of this case.

HEALTH AT THE POST OFFICE.

THE criticism which pursues all public utterances has overtaken that part of the Postmaster-General's annual report which relates to the health of the staff. An article recently published in the *Telegraph Chronicle* takes exception to the report chiefly on account of its want of detail and precision in dealing with this subject. The writer objects, for example, that while apoplexy and pneumonia are represented by a considerable mortality there is no indication of the class of employés affected by them. The same statement is made with regard to phthisis, while it is further evident from the published returns that cases of this disease resulting either in death or superannuation are about one-fourth more frequent than in ordinary life, notwithstanding that Post Office employés are primarily selected persons. The ratio given is 2·2 per 1000, as compared with 1·6 per 1000. It is contended, in the absence of evidence to the contrary, that phthisis is most rife among telegraphists and is attributable to overwork within doors, that it is a preventable disease, and that no steps have been taken for its prevention. Want of precision in treating of sanitary matters is doubtless common to many official reports besides that issued by the Post Office. Nor is the prevalence of phthisis among in-door workers by any means limited to this or other public offices. A greater degree of exactness in the statement of such details is nevertheless attainable without much difficulty and it is certainly desirable as bearing upon the causes and prevention of communicable diseases. Phthisis is an example of particular interest. With regard to it there is certainly no method so effectual as the exclusion of all employés affected by it—necessarily, of course, by a process analogous to superannuation. The physical examination prior to entrance should also, in our opinion, be made to exclude applicants with a markedly phthisical family history.

UNIVERSITY COLLEGE, LIVERPOOL.

LIVERPOOL is certainly much better off than London as regards the ability to get money for scientific researches and other work. The other day at the opening of the Thompson-Yates Laboratories Mr. Glazebrook, the Principal, mentioned that the University College was still in need of a properly equipped anatomy school. His words have borne immediate fruit. At the meeting of the governors of the College held on Oct. 15th the Earl of Derby, President of the College, who was in the chair, mentioned that Professor Lodge was in need of a physical laboratory and that he himself would be happy to give £5000 towards its erection—that is to say, one quarter of the sum necessary. He also said that he had received a cheque for £2000 from Mr. Ralph Brocklebank towards new buildings for the medical school. We learn that the next block of the College to be built includes laboratories, theatre and museum for the study of anatomy, and will cost about £15,000. The citizens of Liverpool are to be warmly congratulated upon their princely generosity. Some day, perhaps, we may arrive at this sort of thing in London, but we fear it will be a long time. London is so vast, so decentralised, that though enormous sums are given every year yet there never seems to be any tangible result, while the average citizen's money is so taken up with compulsory taxes that by the time he has paid his School Board rate, County Council rate, free library rate, baths and washhouses rate, and other things he begins to think that he has done enough.

ANOTHER STREET DANGER.

THE dangers of the London streets are necessarily so many and varied that anything which adds to them unnecessarily should be at once put down with a firm hand. On Oct. 13th Dr. Danford Thomas held an inquest at the Paddington Coroners' Court upon the body of a woman who was knocked down and run over by a coal wagon. Evidence showed that she was crossing Malvern-road, Kilburn, on the night of the 8th inst. when she met with the accident which proved fatal. The driver of the coal wagon said that when he reached the junction of Malvern-road and Cambridge-road a flash-light suddenly came on his horse and made it bolt. The son of the deceased said that the flash-light came from the first-floor front window of a shop. The driver of the wagon did all he could to hold in his horse. A reporter in court informed the coroner that the London County Council are making inquiries as to the use of such lights and a solicitor representing the owners of the coal wagon said that if such lights were to be proved a nuisance and danger an injunction could be obtained to stop their use. A constable said that the shopkeeper had been invited to attend the inquest, but that he had refused to come. A verdict of "Accidental Death" was returned, the jury adding a rider to the effect that they condemned the practice of using lights in this manner. The custom of course is one which should be made absolutely illegal and so also should the use of those illuminated advertisements, of which there are several examples round Trafalgar-square and in Knightsbridge—those, we mean, which light up the street vividly at one moment and leave it in comparative darkness the next.

Digitized by Google

Such alternations are enough to confuse any horse, to say nothing of any unfortunate foot passenger who may chance to be crossing the road at the moment when the light goes out. The roundabout process of getting an injunction is very lengthy and expensive. We are still waiting patiently for the Streets' Bill which we hope the London County Council will one day succeed in getting passed.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

AT the meeting of the Council of the Irish Medical Schools' and Graduates' Association held on Oct. 12th Dr. T. Gilbart Smith was elected Chairman of Council, vice Dr. P. S. Abraham, whose three years' tenure of office will expire at the end of the present month. At the same meeting it was determined to entertain Sir William Mac Cormac as the guest of the association at the autumn banquet, to take place on Nov. 23rd at the Café Monico, with the President, Dr. E. D. Mapother, in the chair.

AN EXTRAORDINARY EXPLOSION AT SEA.

A HOMEWARD-BOUND vessel carrying a cargo of petroleum and naphtha suddenly blew up on Monday last without any apparent warning close to the Tongue bank of the North Foreland. Several lives were lost and the ship speedily became a total wreck. The force of the explosion was enormous, particles of wreckage being hurled 300 ft. into the air. It was stated that the smell of naphtha was so strong during the voyage from New York as to be almost overpowering. Notwithstanding all warning and precautions it is practically certain that in some way or other the vapour became ignited, and this implies that it got access to a naked light. Two points are worthy of notice: first, that the barrels could not have been tight, and, secondly, that the hold in which they were stored freely admitted the escape of vapour to other parts of the ship. Are these conditions in accordance with Board of Trade requirements? Such an inflammable cargo should surely be battened down as tightly as possible in the hold and a proper vent provided. Further, the hold could be filled with carbonic acid gas which now, in the form of liquid in steel tubes, is as common an article of commerce as many other things. These tubes would be useful, too, in a case of fire in the hold. It would probably be more difficult to ensure tight barrels, because however sound they may be at the start the constant rolling of the ship during the voyage introduces the risk of leakage by reason of hoops, staves, and heads getting loose.

POISONING BY ATRIPLEX.

IN a recently issued collection of the reports of the medical officers of the Chinese Imperial Maritime Customs,[1] Dr. J. J. Matignon, of the French Legation in Pekin, gives a lengthy account, in French, of singular toxic effects produced by eating the shoots of the *arroche* (atriplex serrata), a plant belonging to the natural order Chenopodiaceæ and growing abundantly in the gardens and along the walls of the Chinese houses. The sufferers were almost invariably of the lowest social class—mendicants, in fact—and almost invariably females. The principal symptoms were localised œdema of the face, hands, and forearms, impairment of muscular power, of sensation, and of circulation, and dermatitis, often leading to the formation of scars in the œdematous regions. The tops of the young plant are eaten by the Chinese lower class almost raw, embedded in dough, which is made into rolls and gently steamed, or else in the form of salad. All Dr. Matignon's patients said that they had partaken of the plant on an average from ten to twenty hours before the first appearance of the toxic symptoms. These peculiar effects are well known to the Chinese, but they never occur to those who are careful to wash the plant thoroughly and to cook it before eating, which makes it probable that the poison is not inherent in the plant but is perhaps due to an aphis (*pucceron*) found in the shoots. The first cases generally occur in the month of May. The destitute persons who are most liable to be affected do not take the trouble to wash the plant before eating it and the preponderance of attacks among women is probably due to their lower state of health in comparison with that of men. In 1895, when food was very dear on account of the war with Japan, more than 20 cases of atriplex poisoning were treated in the Nan T'ang Hospital; in 1896 food was more plentiful and only 2 cases were admitted; whilst in 1897 there was only 1 case. The attack is sudden and almost always begins with painful swelling of the hands. Œdema of the hands commences half an hour or three-quarters of an hour after the first onset of the painful symptoms; it is, in fact, very probably the initial symptom, resulting from toxic vaso-motor paralysis. Œdema of the face begins a few hours after that of the hands; it usually affects the eyelids, lips, and cheeks, rendering the patient quite unrecognisable in a few hours and totally unable to see for two or three days. Itching of the backs of the hands is almost constant and is felt also in the face; the rubbing and scratching of the patient produce extensive ecchymoses in which there form vesicles filled with yellow serum, and these may coalesce into bullæ as large as a five-franc piece. In mild cases the œdema of the face disappears in two or three days, but when it is well marked it may continue for a week; the œdema of the back of the hands always lasts longer than that of the face and requires at least ten days in severe cases for resolution. The affection of the skin ends either in resolution of the infiltration, accompanied by desquamation of the epidermis, or else in ulceration, which cicatrises slowly. Dr. Matignon points out that there is some analogy between these symptoms and those of both Raynaud's disease and erythromelalgia (Weir Mitchell's disease). A number of experiments showed that rubbing the fresh plant on the hands and face had no ill effect.

THE DIRECT CONVERSION OF COAL INTO ELECTRICITY.

SINCE the transformation of the heat of combustion of coal into mechanical work by the aid of furnaces, boilers, and engines gives a loss of 85 per cent. of the total energy it follows that the production of the electric light by present means is, to say the least, wasteful. In short, it is a roundabout way of utilising the energy of coal by first burning it, then utilising the heat so evolved to convert water into steam, and finally to use the pent-up steam as a propulsive power for the dynamo. The energy thus absorbed and rendered inactive for the final purpose is enormous. If only a short cut could be taken or, in other words, the energy latent in the coal could be employed direct, then electricity would afford a solace to modern existence. The ideal would be a scuttle not to store a convenient supply of coals in, but into which a load or shovelful could be placed as the current required to be kept up. In other words, if the scuttle could be made the generating centre which would work faithfully so long as coal were supplied and containing a fluid which would quietly oxidise the element (for coal is mainly carbon), yielding the chemical energy and hence electric energy of the fuel which could be made available along wires for heating and lighting purposes, the problem of utilising electricity in the house would be solved and gas, wood, and coal and their attendant nuisances for ever banished. It must be admitted that such an attainment would be an ideal and a

Digitized by Google

comfort far beyond all other devices directed towards obtaining a healthy equilibrium in household affairs. Yet such is not beyond the bounds of possibility, for the energies of investigators are being concentrated upon the prospects of being able to turn coal to account for the direct production of an electric current. If coal can be made the positive element in a battery the problem is solved, and this is exactly the direction in which recent investigation has turned, and not without hope. This accomplished, however, everything would depend upon our coal-supply and the time during which it would hold out. Coal is a source of force with which fortunately nature has abundantly supplied us, and by the time this has failed we shall probably have arrived at new methods of utilising natural force, as in the rise and fall of tides and the flow of water, on a scale which will provide the whole community with power and to spare.

PHOTOGRAPHIC EFFECTS PRODUCED BY BACTERIA.

THE "rapid" dry photographic plate with its extremely sensitive film has become a most remarkable aid to knowledge. It has brought countless stars to view which otherwise had escaped observation even with powerful instruments and it has more recently demonstrated the existence of dark light, so to speak—i.e., of radiations which are not realised by the eye, having no apparent effect upon the optic nerve. Recent experiments have shown that almost all substances give off a dark radiation or, at any rate, something which affects the sensitive silver film. This has been attributed to the throwing off of vapour in minute quantity, but sufficiently to act upon the photographic plate in the same way as actinic rays. Dr. Percy Frankland has now shown that certain bacteria have the property of producing images. With some organisms the effect is obtained when the sensitised plate is placed at a distance of half an inch over the culture, whilst when in contact with the film definite pictures of the bacterial growths result. Since the interposition of a piece of glass prevents the action it is probable that the action is due to the evolution of volatile chemical substances. But with phosphorescent bacteria the phenomenon is evidently a different one, since the interposition of glass makes no difference, the organisms emitting a radiation which traverses the glass easily. It is suggested that it is quite possible that considerable differences as regards activity towards a photographic plate may be found to exist with different bacteria, in which case this property may become of importance in their diagnosis. If the method could be applied to the identification of typhoid fever and cholera bacilli in water its value in the service of public health would indeed be great.

THE SMOKE NUISANCE.

IN Dr. Gwynn's presidential address to the Incorporated Society of Medical Officers of Health, an abstract of which we give in another column, it will be seen that he is dissatisfied with the way in which sanitary authorities neglect the Smoke Acts. As long, however, as magistrates deal with offences under these Acts in the lenient way in which some magistrates do or did deal with them, so long will there be small inducement to sanitary authorities to prosecute. The Public Control Committee of the London County Council has just issued a report in which the various steps taken to deal with the smoke nuisance in London are set forth. We are glad to see that the committee mentions that the view taken by certain metropolitan magistrates that difficulty in obtaining smokeless coal was a reason which justified persons in causing a serious nuisance was to be regretted. In our issue of June 25th we said the same thing when commenting upon a decision of Sir James Vaughan. To say that it is allowable to make black smoke because smokeless coal is unobtainable is absurd. To slightly modify the remarks of Mr. Gilbert's "Mikado," "That's the slovenly way in which these Acts are drawn. There is nothing about not being able to get smokeless coal, or not knowing," but the Act says that "Any chimney not being the chimney of a private dwelling-house sending forth black smoke in such quantity as to be a nuisance shall be deemed to be a nuisance liable to be dealt with summarily." The electric lighting companies were the chief offenders, but the great hotels and restaurants, and at one time the National Liberal Club, were also conspicuous examples of how to foul an atmosphere which is at no time too clear. We hope the London County Council will continue its crusade, for its public health work is beyond reproach.

BRUTALITY AND ALCOHOL.

THE brutality of many of the acts which occupy the time of our coroners and our law courts is becoming serious. It is quite a special feature of the time. We are spending ten or eleven millions a year over popular education, yet every day's newspaper reports some deed which is simply brutal in its coarseness and its causelessness. It does not represent anything deeply malicious in the criminal, but in its vulgarity and brutality it is exceptional and discreditable. Opinion is divided as to the exact explanation of such a state of things at the end of a century unprecedented for its strides in knowledge, in science, and in civilisation. It defies law and the ordinary penalties of law. Politicians, moralists, and sociologists are apparently helpless to control it. Perhaps the two most revolting instances of late have been firstly that of William Carey, aged thirty-two years, who was taken to Guy's Hospital, where he died on Sept. 24th from a fractured skull. The deceased was knocked down during a fight outside the Swan public-house, Old Kent-road, on the morning of Sept. 23rd, and when he fell his head struck the tram lines. According to the *Times* report of the inquest Walter Wood, a labourer, said that he had been drinking with deceased, and they had about twenty half-pints of ale each. After leaving the Swan Carey and some men began quarrelling, with the result of Carey's death. The other instance is in the murder of the young policeman, James Baldwin, by stabs with a knife. John Ryan has been committed for trial for the murder. We offer no opinion as to his guilt; but according to the evidence of Constable Henry Bendall he was the worse for drink and "the crowd were mostly drunken." They gathered round and the police were pelted with pots and cans. The invariable element in all such brutal acts is alcohol. It is sincerely to be hoped that the Royal Commission on Licensing Laws now in existence will take some evidence on the association of such offences with drinking and with the public-house system as at present conducted. The common British working man may be ignorant and at his wit's end when the day's work is done, but he is not the cruel monster which he appears to be in these midnight scenes as he leaves the public-house, and something must be done to prevent such wholesale demoralisation.

THE ROENTGEN RAYS IN ITALY.[1]

ACCORDING to a review by Dr. Emile Boix in the current number of Duplay's *Archives*, one of the latest additions to the series of manuals which, to the number of over 600, have been issued by the well-known Milanese publisher Ulrico Hoepli with a view to the popularising of science, art, and literature, consists of a volume by Italo Tonta on the nature, history, and practical application of the Roentgen rays. The

[1] Italo Tonta: Raggi di Röntgen e loro pratiche applicazioni. 160 pp., 65 figs., and 14 plates. Milan: Hoepli, 1898.

Digitized by Google

author, who has studied his subject in several German schools, adds the experience of others to his own observations and advances certain hypotheses which he has formed regarding the nature of the rays and the effects which they produce. He also discusses their mode of action, chemical and luminous, and is able to find a great many points of analogy between them and lightning. Adopting Crookes's theory that all transmissible physical forces are due to vibrations through ether and matter differing from each other solely by reason of the relative rapidity of the vibrations, he likewise agrees with Roentgen that, whereas electricity corresponds to 33,359,730,750 oscillations per second, the x rays should be included in the category which corresponds to about 300,000,000,000 oscillations per second. But Signor Italo Tonta does not adhere exclusively to the dry bones of science, being evidently of opinion with Horace that *omne tulit punctum qui miscuit utile dulci*, for he quotes the following definition of electricity which was written by Galileo Ferrari in an album at the request of a young lady with scientific aspirations: "Ever since Maxwell showed that luminous vibrations may consist in periodic variations of the electro-magnetic forces and his theory was given an experimental basis by Hertz, who adduced facts to prove that electro-magnetic oscillations propagate themselves as light does, the idea has gone on growing ever firmer and firmer that the luminous ether and the medium where electro-magnetic forces have their seat are one and the same thing. Wherefore, O! maiden, so intelligent and so amiable, who dost ask What is electricity? am I able to reply to thine inquiry. Electricity is not only the titanic agent which tearing athwart the atmosphere terrifies by the crash of its thunderbolt, but also the vivifying agent which transmits from the sun to the earth by means of light and heat the magic of colour and the breath of life, which communicates to thy heart the pulsing of the external world and conveys to thy soul the enchantment of a look and of a smile."

AMONG the victims of the recent lamentable disaster to the Atlantic liner *Mohegan* off the Manacles was, we regret to say, Mr. John Fallows, L.S.A., L.R.C.S. Edin., of Princess-mansions, S.W. The deceased gentleman was acting as medical attendant to a patient who was taking a voyage to America. He was specially interested in laryngology and reported that section of the late meeting of the British Medical Association for THE LANCET.

MR. RIDER HAGGARD'S new story, which Messrs. Longmans will publish in November, is entitled "Doctor Therne." The story, which is told by the principal actor, Dr. Therne, after the final catastrophe, deals with the results of the conscientious objector clause in the Vaccination Act, under which the safety of many thousand children and, through them, of the community, is practically left in the hands of the anti-vaccinationists.

AT the County of London Sessions a man, name unknown, was sentenced to six months' hard labour for obtaining money by false pretences. The prisoner defrauded several medical men by representing himself in letters to be Dr. Alfred Vigne, who is now practising in Buluwayo.

A FATAL case of bubonic plague is reported from Vienna. The patient was an employé at the general hospital and, it is presumed, infected himself from a plague cultivation in the laboratory.

THE next meeting of the Odontological Society of Great Britain will take place on Nov. 7th, at 8 P.M., when the President, Mr. John Fairbank, will deliver his introductory address, and a paper will be read by Mr. Storer Bennett on Ankylosis of Human Teeth to the Jaws.

WE are informed that the council's nomination for the office of President of the Roentgen Society for the year 1898–99 is Mr. C. W. Mansell Moullin, F.R.C.S. Eng.

PRACTICAL HINTS ON CYCLING FOR COUNTRY PRACTITIONERS.

BY J. B. EMMERSON, M.D. DURH.

AS a cyclist of 30 years' standing, having begun upon a heavy "velocipede," before the advent of the "bone-shaker, I may be allowed a few words on this subject.

To a man nearing fifty years of age who for a quarter of a century has ridden constantly on horseback without becoming "hard" it is a matter of surprise that two years' serious cycling should have produced such a state of health as he never enjoyed before and that he is more active than he was at twenty-five; but so it is. The country practitioner used to have few opportunities for holiday-making, but now he can get right away from his work on a Sunday quite independently of trains and without being missed from his practice. If the inevitable patient appears just as he is starting it only means ten or twenty minutes' delay and not the loss of a train and consequently of the whole day's outing. One may drive for years and never see, for instance, a brace of magpies or any but the most distant glimpse of other interesting birds, but it is a curious fact that these evince little fear of a cyclist, as though they are well aware that he cannot carry a gun. At night-time, too, it is most remarkable to watch the behaviour of hares. They will rush out of the hedge and career madly backwards and forwards in the light of the lamp for about a furlong, and then end their gambol by another rush back into the hedge. Partridges and pheasants in the daytime scarcely pay one the compliment of rising. Another delightful result of this development is the repopulation of the roads. Formerly one might drive for several miles without meeting as many people. Now the roads in fine weather wear quite a holiday aspect from the number of travellers of all sorts, who produce quite a cheerful effect, and the roadway itself is scored by the marks of rubber tyres instead of by those of iron carriage wheels. All this has taken place in a very few years. No one who has not been compelled to drive incessantly for many years can conceive the pleasure and comfort of travelling on a ring of air instead of having to endure the constant grind of the iron tyre.

So much for the pleasures of the pursuit, now for the practical and economical side. Formerly the writer kept three horses and needed a groom all the year round. He now employs two horses but these are out at grass for a large portion of the year and during this time only an errand-boy is necessitated at a few shillings per week. The summer day's work varies from 15 to 25 miles, but this distance is generally extended for the sake of getting a little variety. There is never a feeling of fatigue at night as there generally is after sitting all day in a gig, and on the rare occasions when it is too wet to cycle it is a simple matter to hire a trap at an infinitesimal cost compared with that of retaining a horse and man all the time.

When a message arrives in the evening, instead of the annoyance at having to turn out with a horse and man it only suggests a pleasant spin after dinner before sitting down to a smoke. Of course, one does not forget the pleasures of the saddle, but those are emphatically only for the winter months when the ground is soft and the capricious movements of the horse will not throw one into an uncomfortable perspiration. No reasonable amount of work hurts a well-fed horse when the roads are soft, but it is pounding along on the hard roads in the summer that knocks him to pieces, so that under this system he ought to last at least three times as long as he would under the old treatment.

There are many things in cycling which are only learnt after a long experience, unless attention is specially called to them. For instance, it is the best plan to keep two bicycles, the old one for use when there is a chance of wet or when something has happened to the better one. What

Digitized by Google

can be worse than to come down in the night in answer to an urgent message and to find the tyre deflated? The happy possessor of two machines simply rides off on the other and repairs next day at his convenience.

To the cyclist the dissipated or negligent groom offers no terrors. He can go two miles and back in less time than the most active and willing of grooms could be fetched and a horse put in the trap, and there is no such thing as a forgotten whip or a rein not passed through the terets.

It is a good plan to have a nice roomy cycle-room instead of pushing the machines away into the coachhouse or the coalhouse, and many an agreeable half-hour can then be spent in touching-up and altering the position of the saddle or varying the arrangements generally. It is better always to stand the machine on the floor leaning against a wall, for if there is a tiny puncture the weight causes the air to ooze out and the condition of the tube declares itself in the morning. Otherwise if the cycle has been on a stand all night one may ride away for a mile or two without detecting the mischief. The first time that the tyre is removed it is well to write the owner's name and address upon the inside of it. This offers an unsuspected means of identification when it is stolen and the thief, after altering its external appearance, vows that he has been riding it for the last six months.

After enduring the discomfort of the perineal pressure produced by the ordinary type of saddle for some time the rider probably changes to another saddle—say, a Christy—and he is delighted with the firm seat and the absence of obtrusiveness in the peak, together with the cooling effect of the air-channel up the centre. After a time, however, he realises that the spring is too tough and that the stuffing has settled hard. The bolt and nut fixing the spring underneath the peak should be removed and replaced by a lashing of whipcord. This allows a much greater amount of play in the spring. A tuft of horsehair should be tied upon the saddle and a Jaeger pad, costing 2*s*., should be placed over this. The result is an ideal saddle. It is well to bind the pad with some broad elastic, so as to grip the saddle firmly.

All tiny tool-bags on the handle-bars and rattling pumps on the diagonal should be banished. There should be only one receptacle for all appurtenances which you need to carry and the best form is in the shape of a schoolboy's satchel strapped behind the saddle. It should contain a repairing outfit and a short pump for emergencies, with a wrench, a box of matches, and a light alpaca overcoat which will roll up into a small ball and is excellent for turning a cold wind or a shower, and, finally, a small "rubber" or openwork towel with a spare handkerchief. The alpaca coat is much preferable to an indiarubber mackintosh, which produces untold misery from retained perspiration and is a fruitful cause of chills, and a regular wetting while moving is safer than this form of vapour-bath.

All the pumping should be done in the cycle-room with a long pump before starting, and then the short-pump mentioned above is all one needs for a sudden requirement. A toy looking-glass of a couple of inches diameter in the pocket is very useful. Holding this up in front the rider can easily survey the whole road behind him, and when followed by his wife or other tutelary deity he can see that all is well with her.

It is a mistake which every rider may have to regret to coast down very steep hills. It is much better to keep the feet on the pedals and to apply the brake lightly. With a well-made brake it is surprising how little harm is done to a good tyre, which ought to stand this treatment for a couple of years, and after all it costs only 30*s*. to replace it when worn out. Besides it is the back tyre which really endures all the hard work. On the other hand, one should take advantage of every slight declivity to put the feet on the rest. It is wonderful how slight a fall in the road will take the machine along at a fair pace, almost as fast as though the legs were trundling round, and the more backward position along with the short resting time is quite a pleasant change.

Flies and dust are often a cause of great annoyance. If a cheap pince-nez be procured and the glasses broken out the openings can then be covered with black crape. This makes the best screen from the glare of the sun and is most cool and comfortable to wear, as the air rushes through and a gale will not blow it off.

The best shirt to wear is one of white flannel, along with linen collar and cuffs and a bright tie. With the bright tie a little of the flannel which peeps out above a high waistcoat or a Norfolk jacket is not to be detected as not being linen. A full cravat generates too much warmth and suggests the absence of the linen shirt. Of all clothing there is none so comfortable as the "natural wool," which is porous and of a neat, pleasant colour. It should be lined with cashmere and not with cotton or linen. Two suits should be in daily wear so as to change during the day. It is a great luxury and entails very little trouble.

No one now objects to seeing a business man wearing knickers and stockings in the country, but if trousers are preferred they should be turned up neatly twice at the bottom. Clips look bad and they prevent the circulation of the air just where it is most desirable. The piece of box-cloth with the stockings folded thickly over it may be very well for shooting or other walking pursuits, but it forms a most unpleasant hot compress for cycling. It is better to have the stockings drawn up inside the knickers in the plainer and quieter fashion.

For the machine very little oil should be used at once, but it should be frequently applied except to the axles of the wheels which need it very seldom. The chief trouble with any form of lamp is caused not by the quality of the oil but by neglecting frequently to remove the blackened and hardened portion of the wick. In a gale a handkerchief tied bodily over the lamp will still permit a fair amount of light to penetrate it and will prevent the flame from blowing out.

Anywhere where a cup of boiling water can be obtained a good cup of tea can be secured by carrying compressed tea tabloids. When stirred up in the water the infusion is quickly made and all the dust settles promptly to the bottom. Compressed cocoa may be obtained without sugar in sticks like ordinary chocolate. It can be nibbled on the road and is very sustaining. Those who cannot digest milk on ordinary occasions can often do so on a journey. After a good breakfast a rider may go all day by simply stopping here and there at likely farmhouses or elsewhere for a glass of milk. With such a diet there is a constant impression of its being forenoon all through the day, than which nothing produces a greater holiday feeling. There is little desire for smoking after the milk such as there would be after a solid meal, and smoking is injudicious as it relaxes the muscular fibre. Alcohol should be left till the day's work is done and taken only with dinner at night. The "prairie oyster" is easily carried and may be made in something like the following proportions—six eggs, three tablespoonfuls of vinegar, a teaspoonful of salt, and a sprinkling of pepper. This should be whipped up and will go into a half-pint bottle.

The craze for high gears seems to be a great mistake. In this windy climate there are few days on which the cyclist will not have to encounter a head-wind somewhere, and with a gear of 63, he can easily ovecome this and mount any ordinary hill without difficulty. On a long hill it is an absurd waste of power and a trial to the machine to ride up. It is better to dismount and to enjoy the change of exercise in walking up.

In hot weather it is a good plan to take every opportunity of wetting the hair. This has a marked effect in keeping the whole system cool and is a great protection from the sun. Comfortable tweed caps are obtainable for 2*s*. with a cork lining between the peak and the brow where perspiration is apt to be free and disagreeable. For the handles a pair of mittens should be knitted and passed on to the handle-bars. A piece of tape can then be tied round them and the mittens reversed on themselves so as to give a double covering on the handles. This not only moderates vibration but is warm in cold weather and does not become clammy or sticky in warm weather.

The backward position of the saddle seems to be overdone. It is better to have it on the front of the T-piece so as to distribute the weight more fairly between the two wheels. In this way the work is easier and puncture of the hind tube less frequent. In conclusion, originality is not claimed for the majority of these suggestions, but they have all been put to the test of practical experience.

BRISTOL ROYAL INFIRMARY.—The half-yearly meeting of the Bristol Royal Infirmary was held on Sept. 27th. The chairman (Mr. Pellew) stated that the expenditure exceeded the income every year by £3000 and there was at present an adverse balance of £13,000 against the institution. The committee had decided to enlarge the Nurses' Home in Terrell-street. The cost would be about £5000.

THE GUILD OF ST. LUKE.

ON Wednesday, Oct. 19th, the Guild which takes its name from Saint "Luke the beloved physician" and has for its objects "the mutual encouragement and support of its members in leading the purer and higher Christian life and the formation of a bond of union to help them in maintaining a true faith, hope, and love amongst themselves and the members of the medical profession" attended a Festal Evensong at St. Paul's Cathedral. The service was announced for 7.30 P.M., but long before that hour all the available chairs in the sacred edifice were occupied by members of the medical profession, and their friends, except those reserved for the 500 medical men in their gowns and robes and a contingent, numbering 150, of the London companies of the Volunteer Medical Staff Corps. Two silver cornets announced the arrival of this latter part of the congregation, who slowly filed up the aisle preceded by the banner of the Guild and that of St. Mathias. The service commenced with the processional hymn "Christ is made the sure foundation" and the ordinary evensong followed. The sermon was preached by the Bishop of London and the service was conducted by the Rev. C. Kelly. Dr. T. W. Belcher, M.D. Dub., and Canon Newbolt read the lessons, which were taken from Ecclus. xxxviii. and St. Luke xiii.

The Bishop, who took for his text the words from St. Paul's Epistle to the Philippians, ch. iii., v. 21, "Who shall change our vile body that it may be fashioned like unto His glorious body," said that in the Apostle's day as now there were two classes of persons—first, those who though they called themselves Christians minded earthly things, and, secondly, those who accepted a higher order of things than that which was seen. In the Revised Version of the New Testament the text read: "Who shall fashion anew the body of our humiliation that it may be conformed to the body of His glory." The difference between the two versions could be accounted for by the fact that at the time the first translation was made men's moral aspirations did not harmonise with their knowledge. Just in proportion as medical science, anatomy, and biology had revealed the true functions of the body we had got back to that noble view of the body and its place as expressed in St. Paul's words. The Apostle's spiritual insight enabled him to see that the body of our low estate was but a temporary form which was capable of receiving a permanent form. We wanted an ideal. Medical men strove for a perfectly healthy mind in a perfectly healthy body. But unless a man did his own part in the work there could be no real progress in his powers and no real elevation of himself into a higher and better being. In Christ they had the ideal they sought for. Speaking of the resurrection the preacher said he had heard that an eminent biologist had said that if there was a resurrection it must be a resurrection of the body. Body and spirit were so intimately connected that one could not be conceived of as existing in a perfect state without the other. If we thought about the matter we should see that the body would be stamped with the impress of all our thoughts and actions. Man was surrounded by laws which he was continually forgetting and breaking. It was the physician's duty to teach him the law. The Bishop concluded his sermon by pleading for support of the scheme which the Guild was trying to put on foot that the benevolent influences of the medical profession might be carried elsewhere by training up men who would spread the message that our body of humiliation was capable of receiving the marks and conformation of "His glorious body."

HEALTH OF BELFAST.

THE report of the Medical Officer of Health of Belfast, presented to a meeting of the Public Health Committee on Oct. 13th, shows that the death-rate for the week ended Oct. 8th had been from all causes 30·1 and from the principal zymotic diseases 7·9. The total number of deaths registered had been 176, of which 38 were attributed to phthisis and diseases of the respiratory system, 25 to enteric fever, 14 to diarrhœa and dysentery, 4 to diphtheria, 2 to whooping-cough, 1 to scarlet fever. 56 of the deaths registered were those of children under one year of age, and 34 were those of persons over 60 years of age. There were 151 cases of typhoid fever notified during the week, the previous five weeks' notifications having been 114, 247, 276, 271, and 333 respectively, the last and highest figure being that for the week ended August 27th. These statistics show, we are very glad to say, a distinct improvement in the decline of the typhoid fever outbreak, but we hope that the public will not be lulled by them into the belief that the so-called epidemic is a thing of the past. What the Public Health Committee must clearly understand is that until the disease ceases to be endemic in Belfast they will be held accountable, and that to get rid of typhoid fever as a disease which "has come to stay" in that city the Public Health Committee must overhaul the whole sanitary arrangements of the city, including the main drainage system, build a new infectious diseases hospital, and adopt all those sanitary and public health measures which every city of half the size of Belfast in England has done years ago. At a previous meeting a numerous deputation, representing the Association of House and Land Agents, Belfast, waited on the Public Health Committee and proceeded to point out that overcrowding and dirt were in their opinion pronounced enough among the tenants of small house property to cause sickness, and complaining that when drains became stopped or houses insanitary through the carelessness or gratuitous dirtiness of the inmates the owners of the houses were made liable. Frequently drains were blocked up maliciously by the tenants, and the deputation urged that it was most unfair that the owners should be held responsible for insanitary conditions following such acts. What the deputation asked was that the Public Health Committee should coöperate with the agents to induce greater cleanliness and care on the part of the occupants of the houses. They asked that when the sanitary inspectors found that a person kept a dirty house to the public danger they should proceed against him. The chairman pointed out that the agents in such cases had the remedy in their own hands and should apply it by giving the parties notice to leave. The power of the Public Health Committee in regard to occupiers is very limited and in the case of weekly tenants it is simply *nil*. The committee also discussed the question of the horrible houses without back passages, through which filth has to be carried from the midden to the front entrance, and they ultimately decided to take proceedings against the owners of such houses in order to compel them to put in water-closets instead of the existing ashpits. It was suggested that the deputation of the house and land agents previously heard was a counterblast directed against action of this kind on the part of the committee which they have reason to apprehend. We are pleased to be able to report that the Belfast Water Commissioners have, in order to remove any suspicion, decided to promote a Bill for the purpose of obtaining powers to acquire compulsorily so much of the catchment areas of their works as may be requisite to guard more effectually the water-supplies of the city against the possibility of pollution. This proposal applies only to the Woodburn and Stonyford supplies, as provision has already been made for the purchase of all the lands included on the gathering grounds of the gigantic Mourne scheme, from which in two or three years there will be a very abundant supply of capital water for Belfast. This action of the Water Commissioners is all the more praiseworthy and far-seeing, since the present typhoid fever outbreak has never been shown to be due in any way to contaminated water and the report of Professor Frankland as to the water during the past three months is very satisfactory. We are also glad to note that the Public Health Committee were firm with a deputation of women who appeared before them and urged that as they had no other means of livelihood than pig-keeping (though there is not back passage accommodation to their houses) they should continue the practice by which they live. The committee informed them that the pigs must go but that they would be allowed a short time so as to dispose of these precious animals to the best advantage.

A NEW WORKHOUSE INFIRMARY.—At the meeting of the Thornbury (Gloucestershire) Board of Guardians held on Oct. 14th it was decided to erect a new workhouse infirmary. The building is estimated to cost £3675 and will accommodate 28 patients.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Plumstead Sanitary District.—Some friction arose in the district during 1897 with the London School Board in consequence of an effort being made by the medical officer of health to examine the children in one of the board schools, an examination which was confined to an inspection of the face, ears, throat, and hands of each child. The teacher, after allowing the inspection for some time, requested the medical officer of health to desist until she could report the matter to the London School Board. This she did in due course, and as a consequence a letter was sent to the Plumstead Vestry "severely censuring" the medical officer of health for inspecting the children. Unfortunately a medical officer of health possesses no legal power to thus examine the school children at school, and hence it would appear to be the safest course to intimate to the school authorities his desire to conduct such an inspection in the interest of the public health. As Dr. Sidney Davies observes, it is clearly in the interest both of education and of health that such inspections should be made, and a medical officer of health after having thus inspected the children must have a much clearer idea as to the desirability or the reverse of advising his sanitary authority to order the closure of a school.

Bedfordshire County District.—The estimated population of this administrative county at the middle of 1897 was but 169,469; its birth-rate was 25·3, and its death-rate 15·2 per 1000, the infantile mortality being 130 per 1000 births. As regards the control of infectious diseases this county is, as a whole, very much behindhand, in spite of the fact that compulsory notification has been adopted by all the sanitary authorities save that of Leighton Buzzard. There are many districts without any proper isolation accommodation, and only two urban districts have ambulance provision. So, too, with regard to disinfection the arrangements are not such as to inspire confidence. The county council have taken some action as regards sanitary improvement during the year, b it their efforts do not appear to have borne much fruit. The county of Bedfordshire is not, in fact, making such advance in sanitary matters as the appointment of a consulting county medical officer of health might have led us to anticipate. Dr. Leonard Wilde gives in his report a summary of the sanitary requirements of each district within the county, and we trust that by next year he will be able to chronicle more progress. The sanitary authorities cannot plead ignorance as to the necessities of their district.

Wandsworth District.—The several medical officers of health congratulate the Board of Works upon the sanitary condition of this district. In spite of the area becoming more thickly populated they are unable to discover in the mortality returns any evidences of the bad effects of the increased density of the people. In referring to the water-supply the medical officers of health report that in November of last year specimens of young horseleeches were found in the tap water drawn from two houses in the district. Investigation of the circumstances was made both by the medical officers of health and by the officials of the Lambeth Water Company but no light could be thrown on the occurrence. It is added that the domestic cisterns from which the water was drawn were quite clean. It is certainly disappointing that the officials of the water company were unable to offer any suggestion as to the means by which the leeches obtained access to the water.

Warwickshire County District.—Dr. Bostock Hill, who, as usual, summarises the annual report of this county (population 336,219), is gratified to notice that there was during 1897 a much larger estimated increase in the population of the rural districts than has been the case for many years previously, the increase being almost as marked in the rural districts as in the urban. As he observes, however, the figures are only estimates and we must wait till the next census to ascertain the real facts. The birth-rate of the administrative county for 1897 was 28·7 per 1000, the rates for urban and rural districts being almost identical. The general death-rate was 15·2 and the zymotic death-rate 2·0 per 1000. Measles caused 109 deaths, as against 41 from scarlet fever and 54 from diphtheria; but in spite of this fact measles is not now notifiable in any district in the county, the borough of Sutton Coldfield having recently abandoned notification of this disease. The Rugby Urban District Council is still recalcitrant in the matter of notification and hence the county figures of notifications are incomplete. No progress seems to have been made during 1897 in the direction of isolation accommodation, but there has been a diminution in the matter of river pollution and improvements have been made here and there in water-supply. Dr. Hill strongly urges the sanitary authorities themselves to undertake public scavenging, and he insists upon the importance of maintaining the soil as free from pollution as possible.

Oldham Urban District.—Mr. Tattersall, in presenting his last and parting report on this district, expresses his regret that the ratepayers threw out the proposed Bill which was to convert the existing excrement disposal system into one for water carriage, and we can well understand how disappointing it must be in these days to find the public still wedded to conservancy methods, more especially having regard to the recent investigations on the growth of enteric fever bacilli in polluted soil. Mr. Tattersall has left to the people of Oldham a memorial of his energy in the shape of a very carefully prepared life-table which will form a valuable standard of reference for future workers in the district. The expectation of life in Oldham is well shown in the form of coloured charts, where it is compared with the figures for Manchester, Brighton, and England and Wales as a whole. Briefly summarised the tables and charts for males show that at birth the expectation of life in Oldham is two years greater than that in Manchester or in Glasgow and seven years less than that in Brighton or in England and Wales. At ten years of age expectation in Oldham is a year more than in Manchester, almost identical with that in Glasgow, and five years less than that in Brighton or in England and Wales. At the age of fifty-five years expectation in Oldham is some six months more than in Manchester, a year less than in Glasgow, and three years less than in Brighton or in England and Wales. As regards females, the relationship of Oldham with the several towns just mentioned is almost identical with that obtaining in the male sex. Considering that the population of Oldham is well paid, well fed, and well housed Mr. Tattersall is surprised that Glasgow compares so favourably with Oldham and that Oldham does not compare more favourably with Manchester. He thinks that the exposed position of the town and the fact that it is built upon clay may account for the excessive mortality amongst the old people. As a standard up to which Oldham is enjoined to work Mr. Tattersall furnishes a column in his tables of the figures for the healthy districts of England and Wales.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6442 births and 4091 deaths were registered during the week ending Oct. 15th. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 24·6 to 20·5 per 1000, further fell last week to 19·0. In London the rate was 18·5 per 1000, while it averaged 19·4 in the thirty-two provincial towns. The lowest rates in these towns were 10·2 in Brighton, 11·7 in Croydon, 13·1 in Portsmouth, and 13·2 in Cardiff; the highest rates were 25·1 in Manchester, 25·6 in Salford, 25·7 in Sunderland, and 28·5 in Norwich. The 4091 deaths included 618 which were referred to the principal zymotic diseases, against 1119 and 774 in the two preceding weeks; of these, 377 resulted from diarrhœa, 74 from diphtheria, 63 from "fever" (principally enteric), 43 from measles, 38 from whooping-cough, 22 from scarlet fever, and 1 from small-pox. No death from any of these diseases occurred last week in Croydon; in the other towns they caused the lowest death-rates in Oldham, Birkenhead, Brighton, and Huddersfield, and the highest rates in Hull, Salford, Sunderland, and Norwich. The greatest mortality from measles occurred in Sunderland and Norwich; from scarlet fever in Derby; from whooping-cough in Halifax; from "fever" in Salford and Sunderland; and from diarrhœa in Manchester, Norwich, Hull, and Sunderland. The 74 deaths from diphtheria included 41 in London, 8 in

Digitized by Google

Leeds, 3 in West Ham, 3 in Cardiff, 3 in Swansea, 3 in Birmingham, and 3 in Sheffield. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals on Saturday last, Oct. 15th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on the same date was 2728, against 2353, 2459, and 2606 on the three preceding Saturdays; 357 new cases were admitted during the week, against 288, 300, and 358 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 200 and 226 in the two preceding weeks, further rose last week to 263, and were 12 above the corrected average. The causes of 39, or 1·0 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Bradford, Leeds, Hull, Newcastle-upon-Tyne, and in sixteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Nottingham, Liverpool, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·1 and 20·6 per 1000 in the two preceding weeks, further rose to 20·7 during the week ending Oct. 15th, and exceeded by 1·7 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·6 in Aberdeen and 18·6 in Dundee, to 22·6 in Glasgow and 28·1 in Greenock. The 625 deaths in these towns included 54 which were referred to diarrhœa, 19 to whooping-cough, 12 to "fever" (principally enteric), 8 to diphtheria, 7 to scarlet fever, and 5 to measles. In all, 105 deaths resulted from these principal zymotic diseases, against 127 and 123 in the two preceding weeks. These 105 deaths were equal to an annual rate of 3·5 per 1000, which was 0·6 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had declined from 110 to 62 in the four preceding weeks, further fell to 54 last week, of which 27 occurred in Glasgow and 14 in Edinburgh. The 19 deaths from whooping-cough corresponded with the number in the preceding week, and included 12 in Glasgow and 4 in Aberdeen. The deaths referred to different forms of "fever," which had been 14 in each of the two preceding weeks, were 12 last week, of which 9 occurred in Glasgow and 2 in Greenock. The 8 fatal cases of diphtheria showed a slight further increase upon recent weekly numbers, and included 3 in Glasgow and 3 in Dundee Of the 7 deaths from scarlet fever 4 were recorded in Glasgow; and 3 of the 5 fatal cases of measles occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 87 and 105 in the two preceding weeks, further rose to 141 last week, and exceeded by 19 the number in the corresponding period of last year. The causes of 40, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the five preceding weeks from 30·7 to 22·1 per 1000, rose again to 24·9 during the week ending Oct. 15th. During the past four weeks the rate of mortality in the city has averaged 24·9 per 1000, the rate during the same period being 19·7 in both London and Edinburgh. The 167 deaths registered in Dublin during the week under notice showed a increase of 12 upon the number in the preceding week, and included 18 which were referred to the principal zymotic diseases, against 38 and 19 in the two preceding weeks; of these, 11 resulted from diarrhœa, 3 from "fever," 2 from scarlet fever, 1 from measles, 1 from whooping-cough, but not one either from diphtheria or small-pox. These 18 deaths were equal to an annual rate of 2·7 per 1000, the zymotic death-rate during the same period being 2·2 in London and 3·9 in Edinburgh. The fatal cases of diarrhœa, which had been 27 and 14 in the two preceding weeks, further declined to 11 last week. The deaths referred to different forms of "fever," which had declined from 6 to 2 in the three preceding weeks, rose again to 3 last week. The mortality from whooping-cough showed a further decline from that recorded in recent weeks, while that from scarlet fever showed an increase. The 167 deaths in Dublin last week included 50 of infants under one year of age, and 38 of persons aged upwards of sixty years; the deaths both of infants and elderly persons slightly exceeded those recorded in the preceding week. Four inquest cases and 2 deaths from violence were registered; and 59, or more than a third, of the deaths occurred in public institutions. The causes of 14, or more than 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointment is announced:—Staff Surgeon George H. Foott to the *Howe*, temporary.

ROYAL ARMY MEDICAL CORPS.

Major Wilkinson is directed to proceed to Woolwich for duty, and Captain Heaton proceeds to Gravesend for duty. Lieutenant-Colonel Magill, Coldstream Guards, is granted leave, with permission to go to Turkey and Greece. Captain Wade proceeds from Shorncliffe to Lydd and takes over charge of the Station Hospital and troops. Major Jones proceeds to Deolali to take over medical charge of the Station Hospital.

INDIA AND THE INDIAN MEDICAL SERVICES.

Lieutenant-Colonel Smyth (retired), who has been temporarily re-employed as a Civil Surgeon in Bengal, to act as Civil Surgeon of Darbhanga during the absence, on deputation, of Captain Green, or until further orders. Captain Deare, on return from temporary military duty, to be Deputy Sanitary Commissioner, Northern Bengal Circle, but will continue to act as Civil Surgeon of Midnapore until further orders. Lieutenant-Colonel Young has been appointed Principal Medical Officer, Malakand Field Force.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant W. Fletcher is seconded for service on the West Coast of Africa.

VOLUNTEER CORPS.

Artillery: 2nd Durham (Seaham) (Western Division, Royal Artillery): John Charles French to be Surgeon-Lieutenant. 3rd Middlesex: Percival Wood to be Surgeon-Lieutenant. *Royal Engineers* (Volunteers): Submarine Miners: The Fourth Division: James Wilson, to be Surgeon-Lieutenant. *Rifle:* 2nd Volunteer Battalion the Suffolk Regiment: Surgeon-Lieutenant S. J. J. Kirby to be Surgeon-Captain. 2nd Volunteer Battalion the Essex Regiment; Honorary Assistant Surgeon E. P. Gutteridge resigns his commission. 4th (Donside Highland) Volunteer Battalion the Gordon Highlanders: Surgeon-Captain G. B. Currie resigns his commission. 1st Gloucestershire Royal Engineers (Volunteers): Surgeon-Lieutenant-Colonel D. J. Dutton retires under the provisions of Paragraph 111 of the Volunteer Regulations, 1897, with permission to retain his rank and to continue to wear the uniform of his corps on retirement.

VOLUNTEER INFANTRY BRIGADE.

Western Counties: Surgeon-Captain J. M. Harper, 1st Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry), to be Brigade-Surgeon-Lieutenant-Colonel on appointment as Senior Medical Officer to the Brigade.

NATIONAL SOCIETY FOR AID TO THE SICK AND WOUNDED IN WAR.

Lord Wantage, the chairman of the Council of the National Society for Aid to the Sick and Wounded in War (British Red Cross Society), has received from Colonel Young, the society's Commissioner, a telegraphic communication from Cairo in which he states that after conferring with Lord Cromer and the Sirdar as to the best means of showing in a practical form the society's sympathy with all sufferers from wounds or sickness in the recent operations in the Soudan irrespectively of nationality he has placed in the Sirdar's hands the sum of £300 to be applied directly for the benefit of the Egyptian soldiers who have suffered in the campaign and the sum of £200 for the purchase and immediate dispatch to Omdurman, of articles urgently needed for the Dervish wounded, who are being treated by the Egyptian medical staff. Lord

Digitized by Google

Wantage and the council of the Red Cross Society have given their sanction to this application of the funds. The society's steamer *Mayflower* returned to Assouan on Oct. 3rd to bring down the last of the sick from the front. This voyage terminates the society's work of evacuating the sick and wounded and the society's general operations will probably be wound up by the end of this month. It is very gratifying to the council—and will no doubt be to the public also—to learn that the supplemental aid rendered in the Soudan campaign by the British Red Cross Society has met with a very favourable impression in Egypt and the Soudan and has been most highly appreciated alike by the sick and wounded and the officers of the Royal Army Medical Corps.

THE MEDITERRANEAN SQUADRON.

With reference to a paragraph under the above heading in our issue of Oct. 8th stating that some dissatisfaction had been caused among naval medical officers serving with the Mediterranean fleet at the promulgation of an order that every ship is to have a surgeon on board at all hours of the day, we find that the words "a rigid enforcement of the order that every ship is to have a medical officer always on board would practically make a prisoner of the medical officer where there happened to be only one on board a small ship" are liable to misinterpretation, as under the regulations in force every ship bearing two or more medical officers has always to retain one on board, who ministers to the medical requirements of the smaller ships which bear only one or no medical officer; in the former case (that is, when there is only one medical officer) he can take his leave daily except on the occasions when he assumes the medical guard equally with the officers of other ships.

THE BLANE GOLD MEDAL.

The adjudication of the Blane Gold Medal founded for Medical Officers of the Royal Navy has recently been made by the Presidents of the Royal Colleges of Physicians of London and Surgeons of England and the Director-General of the Medical Department of the Navy, and medals have been awarded to Surgeon Francis H. A. Clayton, R.N., H.M.S. *Thrush*, and Staff-Surgeon Percy W. Bassett-Smith, R.N., H.M.S. *Magdala*.

Correspondence.

"Audi alteram partem."

THE ROYAL MEDICAL BENEVOLENT COLLEGE: AN APPEAL FROM THE CHAIRMAN AND TREASURER.

To the Editors of THE LANCET.

SIRS,—The growth of Epsom College within the last decade has surpassed the most sanguine hopes of those interested in its prosperity, and it has now taken its place among the most successful public schools of the country. The distinctions won by pupils of the College at the Universities and medical schools and the success achieved by them in various walks of life, afford convincing evidence of the excellence of the education given within its walls. The large share of academic honours which has fallen to the foundation scholars is a gratifying proof of the efficiency with which the College fulfils one of the chief purposes of its founder. The steadily increasing progress of the College is, however, in danger of receiving a check from insufficiency of funds. Besides providing a first-class education practically free of cost for fifty sons of medical men and exhibitions for several others the institution gives pensions to fifty aged medical men or the widows of medical men. Moreover, in connexion with the College there are other annuities, some of which are for the aged daughters of medical men, and there are also nine presentations to St. Anne's Schools for their orphan daughters. We who, with our colleagues of the governing body, take a deep interest in the welfare of this most necessary and useful institution, therefore earnestly appeal to every member of the medical profession to contribute to its support. When we state that a sum of more than £6000 is expended each year, barely one half of which is at present contributed by the medical profession, it will be granted that the profession does not do all that might reasonably be expected of it for the maintenence of what may justly be called its most important charity. We are confident that these facts only need to be mentioned to ensure a satisfactory response to our appeal. Proverbially charitable to all mankind, members of the profession are not likely to be indifferent to the necessities of their own brethren.

It may be well here to correct an impression which appears to exist in many quarters that the College is solely a charitable establishment intended for the sons of medical men and giving only a narrow scientific training. The school consists for the most part of paying pupils, and these and the foundationers are on a footing of absolute equality both in the class-rooms and in the playing fields. The education is of the most liberal character and is directed not so much to the preparation of the boys for any particular profession as to the development of their intellectual powers in a way which will enable them when the time comes to apply them readily and successfully to the acquisition of special knowledge of any kind. The soundness of the literary training is shown by the fact that in recent years several classical scholarships have been won at the Universities by Epsom boys.

We wish it, however, to be clearly understood that the funds for which we are appealing will not be applied in aid of those of the scholars who are paying pupils. That large section of the school is self-supporting, and here we would only point out to the profession that the numbers of our scholars have been steadily increasing, that more accommodation has been recently provided, and that by sending their sons to the College they will not only secure them a sound first-class education at a moderate cost, but will indirectly assist in the education and maintenance of those who are less fortunate—namely, the foundation scholars and the pensioners.

Like other great schools of England Epsom has its "foundation," but, unfortunately, instead of being like these older schools secure in the possession of a sufficient endowment Epsom has mainly to depend for the purposes of its foundation on a precarious annual income.

It is for the charitable side of the institution (the foundation scholars and the pensioners) that we appeal to the *esprit de corps* of the medical profession and to the generosity of the public which is under a debt of obligation to that profession. Unless a larger measure of public support can be secured than can be counted upon at present the Council will be compelled to make a considerable reduction in their expenditure for charitable purposes. This course, entailing as it necessarily would much privation on many deserving persons, they are most anxious to avoid. It is not much they ask for. An annual subscription of 1 guinea entitles to the privileges of a governor, but smaller subscriptions or donations will be gratefully received. If each member of the profession would give 10*s*., or even 5*s*., a year for a very few years the position of the pensioners and foundation scholars would be placed on a secure financial basis and the Council would be able to improve the school and extend its usefulness still more. We are fully aware that during the last year or two the calls upon every class of the community for contributions to charitable objects of all kinds have been unusually numerous, but we venture to think that it would be difficult to find an institution which, having regard either to the value of the work which it is doing or to the merits of the persons for whom it is done, has stronger claims on the profession and on the public than the Royal Medical Benevolent College, Epsom.

Subscriptions may be sent to our honorary local secretaries; to the bankers, Messrs. Barclay and Co., 19, Fleet-street, E.C.; to Dr. Holman, the treasurer, 26, Gloucester-place, Portman-square, W.; or to the secretary, at the office, 37, Soho-square, W.

We are, Sirs, your faithful servants,
J. FAYRER, Chairman of the Council;
C. HOLMAN, Treasurer;
Oct. 18th, 1898. J. BERNARD LAMB, Secretary.

"THE PRACTICAL APPLICATION OF BACTERIOLOGY TO COMMERCE."

To the Editors of THE LANCET.

SIRS,—My attention has just been called to an important leading article on this subject in THE LANCET of Oct. 1st. In it appreciation is only rightly expressed for the pioneer and admirably organised work carried out by Professor Delépine

Digitized by Google

for the Manchester sanitary authorities and also for similar work undertaken by Professor Boyce in Liverpool. I might perhaps point out that some other municipal authorities have also entered into similar arrangements, though on a smaller scale, with pathological laboratories in their cities. Thus more than three years ago Dr. Spottiswoode Cameron, of Leeds, induced his Sanitary Committee to arrange with the pathological department in the Yorkshire College for the examination of diphtheria and other material and recently we have added to our staff in the hope of extending this very important branch of work.

So greatly has the need been felt by sanitary authorities for this bacteriological assistance that some other cities and towns have endeavoured to get the work done by some of their staff. I have even heard of analytical chemists taking this subject up and professing to be ready to make bacteriological examinations of water, &c.; but surely the requisite knowledge and skill can only be possessed by those thoroughly conversant with, and, what is more important still, constantly engaged in, such investigations. This is a point which is clearly emphasised in your leading article. The minimum requirements on the part of those who would undertake such work are that they should be engaged in teaching these subjects and should also have time and opportunity for research work. I take it that your observations upon routine and diagnostic laboratory work on the one hand and the opportunities for research work on the other must commend themselves to anyone with the least experience of pathological investigations. The importance of sanitary authorities being in close touch with those engaged in pathological and bacteriological work cannot be exaggerated. As far as the provinces are concerned our medical schools are scattered up and down the country and should form admirable centres for public laboratories. The communication between these centres and surrounding towns is of the easiest so that results obtained can be at once communicated by telephone as it is our custom to do in Leeds itself. I think it would be for many reasons a great misfortune if these centres should lose the bacteriological work which sanitary authorities find to become more and more necessary as time advances. The duties of medical officers of health are so multifarious that they can hardly wish to add to them the superintendence of bacteriological laboratories and therefore they would presumably be glad to depute this work to such central laboratories. Another point which is touched upon in your leading article is that of funds, the bugbear of many scientific institutions in this country. By bringing this bacteriological work into such centres as those referred to above the funds are increased, more assistance can be secured, and greater efficiency attained. In addition to this opportunities are thus afforded for the training of pathologists and bacteriologists of whom this country has none too many.

The munificent generosity displayed by inhabitants of our great provincial cities, such as Liverpool, Manchester, Leeds, in giving large sums of money shows that not only the profession but also the enlightened outside public are beginning fully to appreciate the scientific work done in these laboratories. This subject has been engaging my attention for some little time past and I trust that this may be the excuse for the length of my letter.

I am, Sirs, yours faithfully,

The Medical School, Leeds, Oct. 18th, 1898. E. F. TREVELYAN.

"WHAT IS 'FIRST AID'?"

To the Editors of THE LANCET.

SIRS,—Mr. Samuel Osborn's letter defining "first aid" in THE LANCET of Oct. 15th is, I hope, likely to be of good service. There has been a tendency for many years past for classes to wander beyond the limits of the subject in the attempt to master to some extent at least the subjects of anatomy, physiology, medicine, and surgery, in the five or six lessons usually given in each course—an attempt encouraged, I regret to say, by the questions of some examiners, such as: "What is the function of the spleen? or cerebellum? or which is the femoral artery?" First aid is really a subject in itself and the instruction should be kept absolutely within the limits of the subject, the whole range of which is covered by the knowledge of a few simple principles and the practical application of that knowledge. While the scope of the examination should therefore be very limited the standard required for a certificate should be high. The teaching should be in the simplest language and all technical terms should be avoided. It is not necessary that classes should be instructed in the mechanism of the heart or the physiology of respiration, and surely the artery of the thigh is more expressive to a person without technical knowledge than the "femoral artery," and is much easier to remember.

First aid should be considered as quite separate and distinct from anatomy, physiology, &c., and any attempt to include them even in a rudimentary way in first aid instruction is only likely to cause confusion and inefficiency. Every qualified medical man is considered competent to give instruction in first aid, but as it is not altogether easy to compress the essentials in a few lectures and avoid the introduction of matter which, however interesting and instructive, is not strictly relevant, it would be a good thing if the various bodies chiefly concerned in the subject were to nominate representatives to meet and agree upon a scheme of instruction which would ensure uniformity and secure a standard of practical knowledge which though limited would be thorough.

I am, Sirs, your obedient servant,

VALENTINE MATTHEWS.

Suffolk-street, S.W., Oct. 15th, 1898.

"VITALITY."

To the Editors of THE LANCET.

SIRS,—Allow me to remark that for the present I shall be sufficiently occupied in defending my own views concerning *vital phenomena* and therefore do not propose to criticise the admirable work of Professor Virchow, who—with Kölliker and several other observers, including myself—has been constantly during the last fifty years very actively engaged in microscopical investigation in health and disease.

If Dr. J. H. Rowe looks over "Protoplasm," 1870–92, he will find many critical remarks which may interest him and he may perhaps assist progress by commenting upon objections to many doctrines generally entertained which I have been led to offer. I send him a reprint of my views in recent papers in THE LANCET which, like other work of mine, are based upon repeated microscopical *observations* and actual facts which have nothing whatever to do with *Spiritus* and cannot possibly have any "supernatural tinge of the Paracelsian world."

Let us concentrate our attention upon the questions of the origin, structure, formation, mode of growth, and action of organs and tissues which have to do with man's health and disease and death, and man's place in nature, which can be determined by microscopical investigation only.

I am, Sirs, yours faithfully,

Oct. 17th, 1898. LIONEL S. BEALE.

To the Editors of THE LANCET.

SIRS,—In relation to the controversy now running in your columns concerning "Vitality" I should like to call attention to one property of living matter which has hitherto received little attention and has not as far as I know received a name. I refer to what might be called "molecular inertia" or "molecular self-conservation." This property is indicated by the fact that as long as any tissue is alive it remains unchanged but immediately after death under the same conditions begins to disintegrate. Furthermore, I wish to offer reasons (*pace* Professor Virchow) for believing that this property of living matter may not depend entirely upon the intrinsic constitution of the cell, but in part upon the power of calling into action a force or forces not included in the ordinary physical gamut. We know that matter varies much in the power of calling into play the known physical forces. The magnetic ray passes indifferently through a thick stone wall, but is arrested by, and acts upon, a needle on the other side. In the same way it is easily conceivable that living matter has such a molecular arrangement that it is able to arrest ethereal forces of which we have no sensuous cognisance. The familiar phenomenon of a vibrating plate throwing sand into patterns according to its nodal lines is suggestive. Suppose the plate were made to vibrate by means of a resonating gong; at every beat the sand would be approximated to these lines, but if the plate and gong did not resonate this would not take place. In the same way it is not at all

Digitized by Google

improbable that the molecules of living matter are so arranged that their vibrations resonate with some ethereal waves not classed amongst known physical forces. If after the sand has been forced into the nodal lines some of it is disturbed it will as the plate vibrates be thrown back into its former place; the stability of the sandy pattern is dependent on the resonance of the plate with the gong; an external force is arrested and used to produce the result. In the same way it is conceivable that if the molecules of living matter are disturbed the force to which their vibrations resonate may throw back the displaced parts and maintain by external means the stability of the living molecule. Again, if new sand be thrown on the plate this will gradually be forced on to the nodal lines and, as it were, be assimilated with what was formerly there. It is instructive to note that an observer situated on the plate whose vision did not reach the gong and who was deaf would be likely to come to the conclusion that the phenomena he observed were quite explainable by the actions of the forces he saw about him and might not guess at the existence of the gong or the striker. It is possible that this principle plays a great part in development; as the ovum throws off new cells, only those able to keep their stability by resonance of their molecular vibrations with the forces playing upon them would survive and so definite types of cells would be produced bearing the impress of external forces. If we push analogy a step further it is only on the lines laid down by the President of the British Association in his reference to transmission of thought. It is conceivable that some part of the brain should form as it were fluorescent points capable of arresting a subtle force disturbance of which results in our conscious ideation and will power.

I am, Sirs, yours faithfully,

London, Oct. 15th, 1898. T. GLOVER LYON.

To the Editors of THE LANCET.

SIRS,—My remarks referring to the augmentation in the sum of vitality and the transmutation of vitality into known forms of physical force were made on the assumption that Dr. Lionel Beale regarded his "vitality" as a species of force. Dr. Beale, however, tells us in his last letter that vitality is not force, and on this assumption those remarks of mine are of course pointless. He says vitality is "without weight and immeasurable" and "cannot be derived from non-living matter or from force." How are we to reconcile this statement with the facts of evolution? Though we may not yet have completely explained the mode of organic evolution no one can doubt that selection plays a part in the process. Now, it is clear that in Dr. Lionel Beale's view organic evolution must essentially be an evolution of vitality—of that spectral something which is supposed to work through structureless bioplasm and to determine structure and development. One must, therefore, suppose that selection operates upon this mysterious agency and not upon material organisms with their multitudinous physical potentialities. Let us see how difficult it is to realise such a conception.

Inasmuch as every living thing has its own peculiar biological tendencies, each must possess its own special vitality. We cannot, therefore, regard vitality as a single entity. We must assume many vitality-entities—one for every living thing. Such an assumption lands us into difficulties. (*a*) Inasmuch as vitality is immaterial—imponderable, unmeasurable, having neither length nor breadth, not derivable from, nor convertible into, physical force—how can we bring it into relation with space—how locate it? (*b*) What sort of changes do these immaterial entities undergo during evolution? Take any individual *homo*, and trace in imagination his evolution from, let us say, his piscian ancestry. His descent must pass through myriads of vitality, entities, each such entity as we travel down the long ancestral line becoming more and more involved, acquiring greater and greater powers in determining structure and function. Can we, I would ask, form any mental picture of such an evolution—any conception whatsoever of the changes undergone by the immaterial agency in its process of evolution? (*c*) How are we to explain the blending of paternal and maternal tendencies? Are we to suppose that the vitality associated with the nucleus of the germ blends with the vitality associated with the nucleus of the sperm, so as to form a new vitality-entity, or that each vitality, the germinal and sperminal, remains separate and distinct throughout development? Either view appears inconceivable. How, on the one hand, can two immaterial agencies blend into one? And, on the other hand, would it be possible to get proper coöperation between two separate and distinct directing powers unless, indeed, we suppose them to have frequent conferences together?

Like Dr. J. H. Rowe I was interested to find Professor Virchow, in his Huxley Lecture, adopting the materialistic theory of vital phenomena. Dr. Rowe asks who is right, the German or the Englishman? I confess that when the question is thus pointedly put my barbaric sense of patriotism makes me almost hope the Englishman is. We owe much to Dr. Lionel Beale, and it may well be that there is more in his theory of vitality than my narrow vision allows me to see. When brought face to face with the mystery of things one does well to recall those fine words of Hamlet—"There are more things in heaven and earth, Horatio, Than are dreamt of in our philosophy."

I am, Sirs, yours faithfully,

Wimpole-street, Oct. 17th, 1898. HARRY CAMPBELL.

To the Editors of THE LANCET.

SIRS,—Dr. Beale appears to define vitality as "a power working in every part of the living world." But a definition of life might be expressed in the same words. Vitality, then, is life. But life is force. What is force? It is a property of matter. What is matter? Matter, having property, is a relative, unreal, dependent existence. But let us assume matter to be a real existence. The existence of matter has been eternal and it could not have existed without its property. As long as matter has existed that property of it which we call vitality, life, or force must have existed or been inherent in it, a suitable environment causing life as we know it to become cognisable by us through certain sensations felt at our nerve-centres as organs of cognition. As matter never had a beginning life as a property of matter never had a beginning. It would be as vain to hope to understand how this property—life—inheres in matter as to expect to understand how gravitation, light, or heat inheres in matter. Any examination of life, as a property of matter, involves an examination of matter. Can man through the medium of his nerve centres conduct an examination of matter? If we say Yes, then an extreme case would be that in which the man with his own nerve centres has to examine his own nerve centres, his nerve-centres being both subject and object at the same time, which is absurd. The absurdity results from assuming matter to have real existence. An examination of life as a real existence will result similarly in absurdity. A search for the first cause or origin of life, whilst it may help to widen the domain of relative knowledge, must fail, as it has up to now failed, in its object. An inquiry on these lines, if it be for first cause or origin we are looking, will take us round and round a circle for ever but without finding origin. If vitality be the cause of life, what is the cause of vitality? To tell us that vitality "is a power, &c.," does not add to our knowledge.

I am, Sirs, yours faithfully,

B. O'REGAN, L.R.C.P. & S. Edin.

Hackney-road, Oct. 17th, 1898.

"SPHINCTER STRETCHING IN CONSTIPATION."

To the Editors of THE LANCET.

SIRS,—It is indeed interesting to find that sphincter stretching is a well-known method of treatment as the *rationale* of the procedure is by no means apparent. That a superadded constipation due to anal fissure should be cured in this way is to be expected. Mr. Allingham's explanation of the fact in THE LANCET of Oct. 15th (unfortunately I have not his book on Diseases of the Rectum by me) is obvious but beside the mark. To say that fissure starts constipation is an inversion of the true sequence of events. Unquestionably constipation is the commonest predisposing, and the delivery of a hard mass of fæces the commonest exciting, cause of fissure. The difficulty lies in understanding how the original constipation is overcome.

Regarding children I have rarely been able to satisfy myself absolutely that any anus the sphincter of which I have stretched has been abnormally small. It remains that in many cases one must fall back upon the theory of an

Digitized by Google

additional benefit brought about through reflex nervous action.

I am, Sirs, yours faithfully,

Oct. 16th, 1898. SIDNEY VINES.

"ULCERATING GRANULOMA OF THE PUDENDA."

To the Editors of THE LANCET.

SIRS,—I am glad that Lieutenant-Colonel J. Maitland has drawn attention in THE LANCET of Oct. 15th to the close resemblance existing between the disease described by him as "chronic venereal sores" (*Indian Medical Gazette*, May, 1898) and the condition reported on by me as "ulcerating granuloma of the pudenda" (*British Journal of Dermatology*, April, 1887) and described by Messrs. Conyers and Daniels in the *British Guiana Medical Annual* (1896) as "the lupoid form of the so-called 'groin ulceration' of this colony." This disease seems to have similar features both in the East and West Indies. It is noteworthy, however, that Lieutenant-Colonel Maitland insists on the existence of a primary sore in his cases. With Lieutenant-Colonel Maitland's material histological and bacteriological examinations could be readily conducted (if necessary in this country) and might do much to elucidate the etiology of this curious malady.

I am, Sirs, yours faithfully,

Harley-street, W., Oct. 18th, 1898. JAMES GALLOWAY.

"THE 'SATURDAY REVIEW' AND MEDICAL STUDENTS."

To the Editors of THE LANCET.

SIRS,—*Apropos* of the reference in THE LANCET of Oct. 15th to the *Saturday Review* article regarding medical students as a class I can only say that the writer thereof must be as much lacking in knowledge of his "subjects" as in courtesy to a class of young men who, I venture to assert, are "second to none" in both behaviour and the ease with which they are managed if treated properly. I have had ten years' experience and can safely say that I have never met with aught but courtesy and consideration, though the students here are numbered in hundreds. Animal spirits will always be in existence where youth and health are, and who would stifle them when no harm results? The whole secret of the bad name attached to the medical student is to be found in the fact that every young man who finds himself at Marlborough-street after a riotous night, when asked what he is, says "a medical student," though he may never have seen the inside of a hospital.

I am, Sirs, yours faithfully,

FREDERIC H. MADDEN,
Secretary, St. Mary's Hospital Medical School,
Oct. 17th, 1898. Paddington, W.

DR. SAUNDBY'S ADDRESS.

To the Editors of THE LANCET.

SIRS,—In a very interesting and instructive address delivered to the students of the University College, Cardiff, Dr. Robert Saundby, in speaking of the prospects of the medical profession, made use of the following language: "Time will bring the roses to all of you but not to all fame or wealth. But if I cannot promise that you will all become medical baronets or even medical knights I can assure you that there is no profession in which success more certainly attends attention to business or which so good an income can be so readily secured. ..... The clamour for better pay and greater privileges depends in part upon inability to recognise the true position which we hold in society. That position depends mainly upon the public belief that we are a disinterested profession and that belief rests upon the vast amount of public work we do for nothing. But if we follow the advice of some of our friends and seek to put the marked price upon all our services must we not reckon upon a change on the part of the public which may not be to our advantage?" From the point of view of a gentleman who holds such lofty positions as Dr. Saundby does the opinions expressed in the foregoing sentences are no doubt right and proper. But from the point of view of an ordinary general practitioner the sentiments expressed sound simply ridiculous. It is not to be denied that with the competition of specialists, hospitals, quacks, nurses, and midwives an ordinary medical man (even with a strict attention to business) has the greatest possible difficulty in obtaining a bare livelihood. The profession has been exploited far too long by the public and naturally enough the public has taken advantage of the circumstance. It is very grand no doubt for a professor of medicine to talk in this way, but really, Sirs, the time has gone by for the promulgation of such views. Men enter the medical profession to make a decent living in an honourable way, and if after many years of hard toil they do not succeed in making a competency it will be small comfort to be told by learned professors that the failure has been due to the fact that they are bound to consider themselves a disinterested profession, and that it was their duty to do a vast amount of work for the public free, gratis, and for nothing!

I am, Sirs, yours faithfully,

Oct. 13th, 1898. A GENERAL PRACTITIONER.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Water-Supply.

SOME anxiety is felt by the authorities about the water-supply of the town, and warning has been issued with regard to the prevention of waste. The increase in the population of the water district during the last four years has amounted to 15,000 a year, an aggregate of 60,000. The long-continued drought has considerably affected the storage supply and has led to careful calculations as to the result, which is considered as serious. The population receiving the supply is estimated at 715,000 and the average consumption during the last year was 23·17 gallons per head per day. The actual amount distributed is about 19½ million gallons per day, or 27 gallons per head. The great storage reservoir at Shustoke has a capacity of 400,000,000 gallons derived from the river Bourne, which is appreciably affected by the prolonged dry weather of the past few months. About 6½ million gallons are daily taken from deep wells which so far have responded admirably to the demand made on them. Still, the level of the great reservoir has been lowering to the extent of 2 in. a day, a fact which is significant of precaution. Some four years have yet to elapse before the Welsh water-supply becomes an accomplished reality, and until then unless strict economy is practised and the natural rainfall is increased the prospect is by no means devoid of anxiety.

Hospital Sunday.

The collection on Oct. 30th for the present year is to go to the General Hospital. A strong appeal has been issued by the committee of the periodical collections and attention is invited earnestly to the following facts. 1. The General Hospital was opened as far back as the year 1779, and is therefore the oldest charity in the city. During this period it has treated 2,000,000 cases. 2. In the last three years 172,148 patients have been relieved, and of these 13,120 were in-patients. 3. During the same period upwards of 122,000 patients were treated as accidents or urgencies without ticket or payment of any kind, and therefore the hospital may to a very great extent be regarded as a free hospital. 4. These figures show a very large increase on all previous years and in themselves present a cogent argument in favour of a much larger measure of support. 5. The annual income from subscriptions, investments, &c., is about £10,000, while the annual expenditure is £22,000 leaving £12,000 a year to be raised by donations, grants, congregational collections, &c. 6. Since the last appeal for the General Hospital was made the old building has been superseded by a new one at a cost of over £210,000, equipped and furnished with every modern improvement and convenience. The additional number of beds in the new building will, if fully occupied, entail an increased annual cost of over £5000.

The Dental Hospital.

In an address given to the dental students on Sept. 24th Mr. Neale pointed out the remarkable growth of the hospital. In 1880 they extracted at the hospital without anæsthetics 3142 teeth; there was no record of the number extracted with anæsthetics, but there were 493 fillings. There were in all 4170 operations. In 1887 the number of extractions had grown to 10,275. Coming to 1895 they extracted 4450 teeth without anæsthetics and 7133 with anæsthetics; they had,

Digitized by Google

too, 6218 fillings. Last year the number had still further increased. No wonder that the hospital is looked upon as a huge tooth-extracting establishment. Since 1880 the number of students had increased from one or two to 22.

Birmingham Medical School.

The outlook for the present session promises to be more favourable than the previous year, the number of entries having increased. The five-year regulations materially affect the supply, the scant numbers being insufficient to meet the abundant amount of work to be found in the various hospitals.

Oct. 18th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

"Pure" Air in Ancoats.

THERE was a crowded audience at the meeting of the Ancoats Healthy Homes Society on Oct. 13th to hear an address on "Pure Air" from Dr. Worswick. He told his audience that it was quite possible for the people in poor and densely populated districts like Ancoats to be quite healthy if they were not troubled with the dense and poisonous fumes of chemical works. It may be possible, but it requires more intelligent efforts than the dwellers in such districts usually put forth. The districts of Ancoats, Miles Platting, and New Cross are favoured seats of chemical manufacturers, whose presence gives a special character to the climate. The chairman spoke in condemnation of the action of the nine members of the City Council returned for these localities, and said he had been assured that if they took up the matter in earnest something would be done to lessen the evils from which they suffered. A comprehensive resolution was carried which affirmed that the disgraceful condition of the atmosphere in Miles Platting caused by the noxious chemical vapours emanating from the various chemical works in the district demanded the immediate attention of the corporation, and it called upon the representatives of the wards concerned to give more attention to the matter than they had done in the past, and, as the works which manufactured the corporation gas bye-products were (it was said) the biggest offenders by allowing large quantities of sulphuretted hydrogen and other offensive gases to escape and render the district almost unbearable, it called upon the corporation to commence at once to manufacture its own bye-products, believing that such action would not only benefit the ratepayers from a health point of view, but that it would be more economical and better for the working classes. The resolution went on to say that the inclusion of two manufacturers on the Sanitary Committee was viewed with alarm as it was feared that the work of the committee in the matter of offensive trades was in danger of being imitated. The alarm expressed at the presence of chemical manufacturers on the Sanitary Committee is not unnatural because they are chiefly and not very favourably known to these poor people as the producers and disseminators of sickening vapours and vile smells. Perhaps, however, it may not be too much to hope that when the widespread discomfort and injury caused by the diffusion of these products of their scientific ingenuity are brought more definitely and convincingly before them they will turn their undoubted abilities into an entirely new channel and seek to devise means by which their products may be made without at the same time flooding the surrounding districts with evil-smelling and depressing fumes. It undoubtedly behoves the corporation to see to it that while the building by-laws insist on a certain area for back yards and all the other points conducing to wholesome dwellings the air of these yards and dwellings should be fit for respiration.

Moss Side Sewage Farm.

The Moss Side Sewage Farm furnishes an illustration of some of the difficulties met with in the land treatment of sewage. At the meeting of the Urmston District Council on Oct. 11th Mr. G. E. Fryer, the medical officer of health, made a report as to the condition of the Stretford and the Moss Side sewage farms. The former was found "in a highly efficient condition," but the lagoons of the Moss Side farm were offensive and filled with decomposed sewage, and the whole of the tank effluent was being passed on to a small sodden portion of land quite insufficient and incapable of dealing with the sewage. The larger portion of the farm was cultivated for farming purposes. A sample of the final effluent of the farm as turned into the long-suffering Mersey was found to be far worse than the tank effluent. The smell arising from the entire farm was very offensive. The representatives of the Moss Side authorities who were present at the inspection acknowledged but tried to excuse the unsatisfactory state of things and promised an improvement "when their pumps came into operation." At what epoch this may occur is not stated. Moss Side is continuous with Manchester, is mainly residential, and would seem well adapted for the bacterial treatment of its sewage, which is at present a great nuisance to Urmston. No improvement can be expected under the present system "until fresh land is used for filtration and the lagoons cleansed." It is evident that there is still plenty of work close at home before the Mersey and Irwell Joint Committee can restore the former river—to say nothing of the latter—to even a reasonable degree of purity, though it is not much more than a generation ago since salmon and sea-trout were caught in the Mersey about Stretford.

Ancoats Hospital.

At the recent annual meeting of this hospital it was announced that the sons and daughter of the late Mr. James Oliver had undertaken the erection of a new out-patients' department at a cost of nearly £7000 as a memorial of their father and of his work and generosity on behalf of the hospital. It was further stated that a legacy had been received under the will of the late Mr. Thomas Whittaker, chemist, of Ardwick, which would amount to over £3000. Mr. Whittaker was formerly dispenser at Ancoats Hospital and he has left money for the Manchester Royal Infirmary as well as to the hospital with which he was once connected.

Manchester and Liverpool Sewage.

There is the prospect of a very pretty quarrel between the pot and the kettle. At a recent meeting of the Rivers Committee of the Manchester Corporation the question was raised of the proposed attempt on the part of Liverpool to prevent the Manchester Corporation from discharging sludge at the entrance to the Mersey at a point near the north-west lightship, where its discharge was authorised by Admiral Sir George Nares, the conservator of the Mersey. It is really far out at sea, beyond a point where it could affect the City of Liverpool. It is curious that exception should be taken to this when it is stated that "the Liverpool Corporation not only pour their crude sewage into the Mersey close to the landing-stage but also discharge all the solid refuse of the city at the same point at which the sludge is discharged from the Manchester steamer."

Feeble-minded Children.

An address was given by Sir Douglas Galton at Owens College on Oct. 11th, at the opening meeting of the session of the Manchester branch of the British Child Study Association, on "The Educational Management of Feeble-minded Children." He thought it might be assumed that for the future the classification or grading of children according to their intellectual development for purposes of education would be carried on on sounder lines than had been the case hitherto. Excluding the blind and the deaf-and-dumb we had first, he said, the normal bright child, then the dull and backward, the child termed "mentally feeble," and the lower grade of these latter who passed into imbeciles and idiots. He held that individualising the care of the mentally feeble child gave the best hopes of attaining success in its improvement.

Oct. 19th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

New Buildings for the Departments of Anatomy, Medicine, and Surgery, in University College, Liverpool.

ON the occasion of the opening of the Thompson-Yates laboratories in University College on Oct. 8th, Principal Glazebrook made a strong appeal for funds to enable the governors to rebuild the old medical school which has become quite unsuited to the growing needs of the anatomical, medical, and surgical departments. A new dissecting-room is urgently required, as the existing room is fast

Digitized by Google

becoming obsolete and is altogether inadequate for its purposes. The appeal has already been responded to by Lord Derby, the President of University College, who has promised £5000, and by Mr. Ralph Brocklebank, the chairman of the Royal Infirmary, who has sent a donation of £2000. It is computed that a sum of £20,000 will be required for the new building, and with such a favourable start there ought to be no difficulty in obtaining the requisite amount.

Bequest to a Liverpool Charity.

The late Miss Barbara Morison, formerly of Liverpool and late of Penmaenmawr, has bequeathed £500 to the Liverpool Consumption Hospital.

Stanley Hospital.

The Lord Mayor of Liverpool on Oct. 13th laid the foundation-stone of the new out-patient department of the Stanley Hospital, which is being erected out of the funds of the Roger Lyon-Jones Trust. The new building is to be placed on a site adjoining the hospital and will cost £2500. It will consist of consulting-rooms, dispensary, and other requirements and it will be entirely detached from the hospital pile of buildings. The amount obtained from the Roger Lyon-Jones Trust by the Stanley Hospital within the last few years has reached the substantial sum of £6500, the benefit of which cannot be over-estimated.

Professor Virchow's Visit to the Royal Infirmary.

Professor Virchow paid a visit to the Royal Infirmary on the morning of Oct. 8th. He was received by the medical staff and a number of the officials of the infirmary. Professor Virchow appeared much pleased with his visit and frequently expressed his admiration of the general arrangements of the hospital. He was particularly interested in the post-mortem room, and remarked on the purity of the atmosphere. He was also favourably impressed with the circular wards, which are an interesting feature of the building. The Royal Infirmary, which is quite a recent erection, is one of the finest hospitals in the kingdom, and it contains all the most modern improvements. Professor Virchow was accompanied by Sir Samuel Wilks and Dr. Lauder Brunton. On the following day (Sunday) Lord Lister attended Divine service at the infirmary chapel, and afterwards visited the wards accompanied by his host, Mr. E. R. Bickersteth, who is one of the consulting surgeons to the infirmary.

Oct. 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Winter Session in Edinburgh.

EDINBURGH at the beginning of another winter session begins to show that she is recovering from the exhaustion following upon her efforts for the British Medical Association meeting. Many of the men have had a long holiday, but now that classes have reopened they are all at their posts. The session opened on Tuesday, the Oct. 18th. It has been characterised by no special incident beyond the delivery of some class introductory lectures. Some changes have, however, occurred. Dr. James Carmichael's term of office as a physician to the Royal Hospital for Sick Children has terminated and it is expected that one of the extra physicians will be promoted to the vacancy resulting therefrom. This will make a vacancy amongst the extra physicians and for this post Dr. Crawfurd Dunlop, Dr. G. Elder, and Dr. Fowler are candidates. Dr. Muir's appointment to the Professorship of Pathology at Dundee has made a vacancy in the pathological department of the Royal Infirmary, for which there are three candidates—Dr. F. D. Boyd, Dr. Shennan, and Dr. Welsh. The infirmary has lost a valuable official in Dr. Muir, and it is much to be regretted that the authorities interested have not yet seen their way so to remunerate the office of senior pathologist to the infirmary as to enable an expert to make it his main if not his sole work.

Aberdeen Royal Infirmary.

At the next meeting of the board of directors Professor Ogston, who has resigned the office of senior surgeon at the hospital, will be appointed as one of the consulting surgeons and the question of the staff appointments caused by Professor Ogston's resignation will be considered.

Aberdeen and District Branch, British Medical Association.

At the annual general meeting of the Aberdeen, Banff, and Kincardine branch of the British Medical Association held in Marischal College, Aberdeen, on Oct. 15th, Professor Ogston gave a demonstration on the Effects of Modern Bullets on the Human Body. Professor Ogston afterwards presided at the business meeting, at which office-bearers were elected for the ensuing year. Dr. J. O. Wilson (Huntly) was elected President and Dr. Farquharson, M.P., as President-elect. The Vice-Presidents are Professor Finlay (University of Aberdeen) and Dr. G. Trail (Strichen). The annual dinner was subsequently held in the Palace Hotel, Aberdeen.

Proposed Public Slaughter-house, Aberdeen.

The members of the flesher trade in Aberdeen have resolved to adopt a hostile attitude as to this scheme.

St. Andrews University as a Medical School.—The Union with Dundee.

St. Andrews University was opened for the session by an address from Principal Donaldson. In the course of his remarks he observed that better days had begun to dawn upon the University. The numbers of students were steadily increasing and the financial resources of the university were augmented. A clear and satisfactory union with Dundee had been come to and now for the first time they had a complete medical school and a complete medical faculty. This was an immense stride in the effort to gain a high place among the universities of Scotland. The movement for union, which had this year reached its final stage, was justified first of all in the benefit which it conferred on the community. No St. Andrews student need now leave his University to finish his studies elsewhere. If he was attached to the place he could continue in it until he entered upon the duties of his professional life. This meant a great reduction in the expenditure required for education and it meant also that in the more retired locality and in the less numerously attended classes of the University he would get greater attention and have greater opportunities of experiment and research.

The late Dr. Francis I. White.

The news of the death of Dr. Francis I. White, which occurred at his residence in Atholl-place on Saturday, was received with general regret by the community of Perth. The deceased, who was born in 1815, had resided in Perth since 1840. He held several public appointments and his invariable kindness of disposition gained for him friends as well as patients. In ecclesiastical matters he was a prominent member of St. Ninian's Cathedral body. In his house and under his auspices the first meeting for promoting the building of the Cathedral was held so far back as 1846.

Oct. 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mercer's Hospital, Dublin.

A LETTER referring to the subject of the corporation grant withheld, so far, from Mercer's Hospital, has appeared in all the morning papers. It emanated from one of the governors—Mr. Theodore Ryland—and contained what he describes as a practical suggestion :—

> Let the Council, in conference or communication with the governing bodies of all the hospitals usually receiving corporation grants, consider some general scheme for promoting the efficiency of these hospitals, and if application to Parliament be necessary insert a short clause in the next Bill introduced into Parliament authorising the hospitals to comply with the terms agreed upon by all parties. Hitherto the supervision of the corporation has been efficiently exercised by their hospitals committee and it may be worth while to consider whether the committee would freely criticise the management of any hospital on the board of which their fellow-councillors represented the Council.

When it is remembered that the corporation of Dublin have through their hospital committee found fault with the management of Mercer's Hospital and, as a remedy for the quarrels and litigation in connexion with it and the medical staff which have been matter of public comment for years, have resolved upon the strong course of refusing their grant except under specified conditions, it seems to all outsiders improbable that they will consent now to reconsider and revive the scheme under which all their grants have hitherto been made to the hospitals of Dublin at the instance of one of

Digitized by Google

the governors of the institution which has been censured and dealt with in an exceptionally severe way. The *impasse* is therefore likely to continue.

The Housing of the Poor of Dublin.

A public meeting was held on Oct. 17th in the Mansion House in support of the movement for providing houses for the very poor of Dublin. The Right Honourable the Lord Mayor presided and in his opening address alluded to the refusal of the neighbouring townships to join with Dublin in the expense of maintaining the poor of the city. Professor Antony Roche moved:

That in the opinion of this meeting the time has now arrived when it is absolutely imperative that provision shall be made for the housing of the very poor at rents not exceeding 2s. a week.

The Royal Academy of Medicine in Ireland.

The annual general meeting of the Royal Academy of Medicine will be held at the Royal College of Surgeons on Friday, Oct. 28th, at 4.30 P.M., when the report will be submitted and the election of officers will take place.

The Londonderry Asylum.

At a meeting of the governors of this asylum held on Oct. 13th a report was read from a sub-committee of the board as to what would be required for the new asylum buildings at Gransha to relieve the congestion in the asylum by taking over 60 patients. These buildings are situated four miles from the present asylum, on the site of the new asylum to be built for the county at a cost of £110,000. The medical superintendent advised, for economic reasons, that the auxiliary be worked as a branch, stores being daily sent out from the present asylum. They would require one head attendant, seven second class attendants, one cook, and an assistant nurse. The matter was deferred until next monthly meeting, as it was thought wiser to have a full attendance before deciding on a course which would entail such an amount of additional expense.

Infantile Mortality in Belfast.

At an inquest held on Oct. 10th in reference to the death of a child, six weeks old, whose mother had to work in a mill, the jury returned a verdict of "Death from blood-poisoning resulting from improper feeding." The coroner said that in Belfast out of every 100 deaths 25 were those of infants under one year old, and that improper feeding was the cause of one-fourth of those deaths. It is pleasant to say that through the exertions of the Lady Mayoress and Mr. A. W. Vance two crèches have been established and, it is said, the authorities of one of the large spinning mills are shortly to open another.

Opening of the Winter Session, Belfast.

The medical session (1898–99) was opened on Oct. 18th, when Dr. Calwell delivered in the theatre of the Belfast Royal Hospital before a large audience of students and colleagues an extremely interesting and suggestive introductory address on "The Study of Ourselves and our Neighbours," full of original thought and humour and with much practical advice for the guidance of students.

Cork Medical and Surgical Society.

The first meeting for the session of the Cork Medical and Surgical Society was held on Wednesday last and the President, Dr. Edward Magner, delivered the inaugural address. He selected as the subject "University Education in Ireland" and dealt with it mainly as it affects medical interests. He urged the desirability of radical changes which would foster the extension of university teaching. He emphasised the fact that the Royal University is a mere examining board. He protested against centralisation in Dublin as calculated to dwarf national intellectual progress and was strongly in favour of the establishment of universities for the provinces. In favour of the latter project he pointed out that in the German empire there are several universities, many of them located in comparatively small towns, and he also mentioned that in proportion to its population Scotland has a large number of universities. He had no doubt that the great commercial progress of Germany and of Scotland was mainly due to the facilities for university training in those countries. Why should not Ireland have similar opportunities for attaining a high place amongst the commercial nations of the world? In nearly all universities the great majority of the graduates belong to the medical faculty. Hence medical men always did and always will take a deep interest in university extension and development. The political aspect of the Irish university question could not be discussed at a meeting of the Cork Medical and Surgical Society, but as many of the members, either as professors of the Queen's College or as clinical teachers at the hospitals, were intimately associated with medical education they could not fail to be deeply interested in any project calculated to extend the sphere of university training. If the education question were settled once and for all Cork should become a large university centre and the intellectual and material prosperity of the citizens would be assured. Dr. Magner entirely endorsed the opinion of Sir Walter Foster that it would be to the advantage of the profession if its individual members would take a more prominent interest in politics. Medical men might differ amicably in politics and yet work shoulder to shoulder for anything calculated to promote the welfare of the profession at large. Dr. Magner's address is regarded as a valuable contribution to the discussion of the Irish University question and has been fully reported and favourably commented upon by some of the local newspapers.

Oct. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The French Surgical Congress.

THE Twelfth Congress of the French Surgical Association opened on Oct. 17th in the large theatre of the Faculty of Medicine, Professor Le Dentu being in the chair. On the platform were the Dean of the Faculty (Professor Brouardel), Professor Guyon, Professor Bouchard, Professor Poncet of Lyons, the Inspector-General of the Army Medical Staff (M. Dujardin Beaunetz), Professor Jonnesco of Bucharest, Professor Offa of Würzburg, and a large number of surgeons from Paris, the provinces, and foreign countries. Among the audience were MM. J. and A. Reverdin of Geneva, M. Dellettez-Gallet of Brussels, M. Deguins of Antwerp, MM. Doyen, Albarran, Picque, Galeszowski, Boiully, Teuffier, Berger, Legueu, Forgue of Montpellier, Montprofit of Angers, Calot of Berck, Roux of Lausanne, Suarez de Mendoza of Madrid, Ceci of Pisa, and others. Professor Le Dentu opened the session with an address in which he related the advances made in surgery of late years especially with regard to the treatment of tetanus by intra-cerebral injection of antitetanus serum. M. Albarran followed and read in his own name and in that of Professor Guyon an important paper upon Nephrostomy. MM. Teuffier and Bazy opened a discussion upon the matter. After the meeting the members of the Congress adjourned to the Hôtel des Sociétés Savantes, where they witnessed the progress of sundry surgical operations reproduced by means of the cinematograph. The exhibition will be repeated on Oct. 21st when a representation of an abdominal section performed by M. Doyen will be given. On the evening of Oct. 17th a *soirée* was given by M. Le Dentu in the galleries of the Champs Elysées which was a great success. On Tuesday, Oct. 18th, the members spent the morning in visiting the various surgical clinics in Paris. M. Doyen performed sundry operations in his private hospital in the Avenue de Jena, among which were an operation for the relief of an intestinal fistula and removal of the uterine adnexa for double suppurative salpingitis. In the afternoon M. Faure read a paper upon the Surgical Treatment of Facial Paralysis by means of Joining the Facial Nerve to the Spinal Accessory. MM. Abadie, Jonnesco, and Temoin, of Bourges, read papers upon Resection of the Cervical Sympathetic. Wednesday morning will be allotted to the Surgery of the Neck and Chest and the Vertebral Column, the speakers being MM. Calot, Forgue, Legueu, and Redard, and also to questions concerning Anæsthesia and Dressings, in which discussions the following will take part: MM. Berges, A. Reverdin, Teuffier, and Ceci. On Wednesday evening the subjects for discussion will be the Stomach, the Intestines, the Liver and the Spleen; speakers, MM. Doyan, Roux of Lausanne, Dellettez-Gallet of Brussels, Le Dentu, Quenu, Bouilly, Duset of Lille, Delageniere of Mans, and others. Thursday morning will be devoted to Gynæcology and on Friday there will be a discussion upon the Surgical Treatment of Goitre.

Attempted Suicide of Dr. Boisleux.

Dr. Boisleux, who some eighteen months ago was condemned to six years' imprisonment in company with Dr. Jarrige on account of a pregnant patient whom he had curetted having died, is serving his time in the prison

Digitized by Google

at Étampes. He chose confinement in a cell which gives him a remission of half his sentence. This method of punishment, which the average criminal considers far more severe, was really lighter for the prisoner in this case, for by undergoing it he avoided contact with the other prisoners. On the other hand, the French prison regulations allow prisoners who have chosen this form of punishment provisional liberation at the end of half their reduced period of imprisonment if they conduct themselves well. Boisleux accordingly expected to be released at the end of eighteen months, and, when he discovered that he would not be, he became very depressed and tried to commit suicide by opening the veins of his feet and arms by means of a sharp spike of metal broken off his mess tin. A warder, however, arrived in time and Boisleux was removed to the infirmary where he was treated. Eight days afterwards he made a second attempt and he is in a very serious condition.

Treatment of Aortic Aneurysm by Injections of Gelatin.

M. Lancereaux made an important communication to the Academy of Medicine on this method of treatment, which has yielded remarkable results in his hands. The first patient mentioned had an aortic aneurysm which projected anteriorly. Subcutaneous injection of a solution of gelatin in artificial serum was made and the patient got well. Some time previously the blood had escaped from the aneurysm and coagulated just under the skin; the patient's state was very critical, but injections of gelatin promptly brought about coagulation of the extravasated blood. In the second case the patient suffered from aneurysm of the aorta which had not come to the surface. By means of the gelatin injection treatment all the pain disappeared and the dilated superficial veins diminished in volume. M. Lancereaux has treated by this method many aneurysms of the aorta and one subclavian aneurysm with similar success. Two other patients who suffered from aortitis and dilatation presented, however, no amelioration. They died and the post-mortem examination showed that no coagulation had taken place in the dilated portion of the artery. The operative proceeding was as follows. A solution of 2 grammes of gelatin in 100 grammes of saline solution is made and this is injected under the skin of the thigh into the subcutaneous cellular tissues in a dose of 250 c.c. The injection is renewed at varying intervals of time—every two days to fifteen days. As a rule, 10, 15, or 20 injections are quite enough to obtain a complete cure. The communication of these researches gave rise to a long discussion at the Academy, in which M. Huchard, Professor Hayem, and Professor Fournier took part. M. Huchard had employed the method of M. Lancereaux in many cases, one of which was very serious, the pulsation of the aneurysm being very strong. A complete cure was obtained by means of 20 injections and the sole inconvenience attaching to this treatment was that it was very painful. In a patient suffering from phthisis with constant hæmoptysis due to little aneurysms of the kind described by Rosmussen M. Huchard employed the same treatment and succeeded in stopping the hæmoptysis. This, however, did not prevent the patient from dying later from pulmonary tuberculosis. Certain precautions have to be observed in this method of treatment, for a patient, under the care of Boisset, in whom injections had been made on a very small scale lest the blood should coagulate all at once died very suddenly from embolism. The injections must never be made in the neighbourhood of the aneurysmal sac and still less into the aneurysmal sac itself.

Obituary.

Professor Haydenreich, Dean of the Faculty of Medicine at Nancy and Professor of Clinical Surgery, has just died after having pricked his finger at an operation.—Professor Bouchacourt, Professor of Obstetrics of the Faculty at Lyons, has recently died at an advanced age. He was the author of many important works dealing with his particular department of practice.

Oct. 19th.

SWINDON WORKHOUSE HOSPITAL.—At the meeting of the Highworth and Swindon Board of Guardians held on Oct. 12th it was decided that the men's hospital be enlarged so as to accommodate 50 additional beds, to include 2 wards, 1 for special cases and the other for boys, and also that the women's hospital should be enlarged by 2 wards to contain 80 additional beds. The estimated cost of the work is £3000.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Gall-stones.

PROFESSOR KEHR of Halberstadt is well known in connexion with operations on the gall-bladder and has probably performed more operations on this viscus than any other German surgeon. Lately while on a visit to Carlsbad he had an opportunity of discussing the indications for either operative or balneological treatment with the resident medical men of the famous Bohemian watering place, and he has published his conclusions in the *Münchener Medicinische Wochenschrift*. He recommends that every patient without distinction should be sent to Carlsbad first and that operation should only be resorted to when the Carlsbad water has proved useless. According to him no medical man of Carlsbad now believes that the Sprudel water is able to dissolve gall-stones or to bring about their expulsion from the gall-bladder. The undoubted success sometimes obtained by a stay in Carlsbad is due most of all to a judicious diet and to the regulation of the hepatic and portal circulations by the water, whereby the complication of cholecystitis is relieved. The gall-stones themselves remain in the gall-bladder, unless they are of very small size, in which latter case they may be spontaneously evacuated. The complaint thus passes into a latent stage. When this condition is established the patient may feel very well, but fresh attacks often occur and then the calculi may become impacted in the bile-duct, and suppuration, peritonitis, or even carcinoma, may be the sequel. These undesirable effects may, however, be avoided by early operations, which are free from danger if performed before there is impaction of gall-stones or adhesion of the gall-bladder to surrounding structures. With these precautions 160 operations have been performed without a death due to the operation. From a theoretical point of view early operation is indicated in every instance provided the surgeon's object is really to cure the complaint and not merely to be content with relieving the pain. Routine methods must be avoided and the age, the constitution, and the social position of the patient must be considered. For instance, patients over sixty years of age ought not to be operated on unless their lives are in danger; well-to-do persons with slight biliary colic, who are able to obtain proper food, may wait some time. Professor Kehr considers that internal treatment is indicated (1) in cases of acute occlusion of the ductus choledochus without fever; (2) in cholecystitis with or without icterus; (3) when calculi are discharged spontaneously during the attacks of colic, but when no calculi are discharged operation is indicated; and (4) in cases combined with diabetes or gout or when other affections make the administration of an anæsthetic undesirable. A course of Carlsbad treatment is of great benefit after an operation has been performed. When the calculi are in the ductus choledochus, cholagogues, such as olive-oil, glycerine, and salicylate of soda, may be used; when the calculi are still in the gall-bladder and an operation cannot be performed attempts must be made to relieve the inflammation. The endeavours of the physician to make the calculi pass through the narrow duct into the duodenum are much more dangerous than the removal of the calculi by laparotomy. An operation is indicated in every instance (1) of acute sero-purulent cholecystitis; (2) in adhesion of the gall-bladder to the intestines, the stomach, &c., provided that pain has been felt; (3) in chronic occlusion of the ductus choledochus or cysticus; (4) in originally slight cholelithiasis, where the pains have continued notwithstanding internal treatment; (5) in purulent cholangitis; (6) in perforation of the biliary passages and peritonitis; and (7) in morphinism caused by cholelithiasis, where an operation must be performed previously to the treatment of the morphia habit. It is thus not easy to settle the indications for balneological or surgical treatment and a very exact diagnosis, including a reference to the patient's age, constitution, &c., is necessary before deciding whether the Carlsbad treatment or an operation will best suit the individual case.

A Large Nose made Smaller.

In the *Berliner Klinische Wochenschrift* Dr. Joseph describes a rhinoplastic operation performed by him, not, as is usually the case, for the purpose of restoring a missing or mutilated nose, but in order to reduce the proportions of a preternaturally developed nose. A country gentleman possessed an olfactory organ of such unusual dimensions as

Digitized by Google

to excite the hilarity of his neighbours, and he was thereby so mortified that he well-nigh became melancholy, and appealed to Dr. Joseph to deliver him from this affliction. The superfluous skin and cartilages were accordingly removed by four incisions, which formed two angles with the vertex in the median line of the nose; then the unduly prominent nasal bones were reduced with the chisel, and finally the bridge of the nose was shortened by excising a wedge-shaped portion of bone. Sutures were then applied, the wound healed by first intention, and the patient is now in high spirits, a comparison of photographs affording ample evidence of the improvement which has been brought about in his appearance. A similar case has been under the care of Professor Robert Weir of New York and is described in the *New York Medical Journal*, 1892, page 452.

The Battle of the Clubs in Rhenish Prussia.

By the trades laws in Germany membership of a sick club is compulsory on every working man earning less than 2000 marks (£100) a year. The sick clubs are under the control of the Government, but are, of course, entitled to manage their affairs themselves provided they do nothing contrary to the laws or regulations. In places with a large working-class population the influence of the clubs and of their committees is very great, as there are clubs consisting of from 40,000 to 50,000 paying members, not including their families. The presidents, secretaries, treasurers, &c., nearly always either actually are, or have been, working men, and they often exercise an authority over the medical men which is far from being satisfactory; often also the appointment of a medical man is decided not by the ability but by the political views of the candidate. Controversies between the club medical officers and the committees are therefore not unfrequent and a variety of proposals have been made with a view to guaranteeing the independence of the medical officers. The so-called "free choice" system, which has been described by me in THE LANCET, has given the best results for the profession, but the great majority of clubs have hitherto declined to adopt it. A serious disagreement broke out lately at Remscheid, in Rhenish Prussia, in connexion with a workmen's sick club, which includes nearly all the working men of the town, the committee having, without any sufficient reason, discharged some of the medical men who had hitherto attended the members. The local practitioners also discovered that the committee intended in course of time to dismiss them all and to bring into the town medical officers of their own, who would not engage in private practice, but would receive good salaries for devoting themselves exclusively to the club members and their families. In this way the old-established medical men would lose the not inconsiderable part of their income which had been derived from the club practice, whilst their successors not having the support of private practice would be entirely dependent on the club. Negotiations having failed the local practitioners, in order to put pressure on the committee and to draw public attention to these facts, took a very decided step. Without previous notice they declined to attend club members, club patients who came for advice were sent away, and requests for visits at the houses of patients were ignored. This action, however, unfortunately proved unsuccessful. The club committee stationed club members in front of the medical men's houses to warn off patients, and in urgent cases these sentries or pickets provided patients with money to consult other practitioners of the neighbourhood not concerned in the dispute. Telegrams were also sent to individuals who had previously sought to be appointed and in twenty-four hours sufficient medical aid was at the disposal of the members. The proceedings in Remscheid caused a sensation in Germany and a Government Commissioner was sent there with instructions to mediate between the parties, but as further negotiations were declined by the club and as the committee had not acted contrary to its by-laws he had to retire without having accomplished his purpose. The medical men who had bravely struggled to uphold the honour of the profession have therefore had the worst of the contest through not markedly considering the overcrowding and the disunion in the profession which enabled their opponents to fill their places. They, however, succeeded in drawing attention to the difficulties of their position, one result being that the press, in discussing the question, is mostly of opinion that the trade laws have made German medical men too dependent on the clubs and that the appointment of club medical officers ought to be under official control and not left to private agreement.

Oct. 18th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Recrudescence of Typhoid Fever.

IN Italy the poor are always with us and, in proportionate degree, infectious maladies. Indeed, the two facts originate in the same cause. The poverty that withholds work and wages from the humble breadwinner prevents communes and municipalities from carrying out the sanitary regulations imposed by Government and so beggary and disease can claim a common parentage. In not a few parts of the kingdom typhoid fever has reappeared in epidemic form so pronounced that the Pelloux administration can no longer shut its eyes to the danger. "Many communes," so runs the authoritative announcement, "are so badly furnished with *acqua potabile* that explosions of typhoid fever are inevitable. The drainage system in these localities is so bad as practically to be non-existent. The drinking water is contaminated accordingly, but besides the 'infiltrazioni micidiali' (deadly infiltrations) thus induced there are other factors that make for typhoid fever with hardly less power. Means of house disinfection are absolutely wanting. Isolation of the fever-stricken is neglected for lack of accommodation. The 'locali di ricovero' (places in which the homeless are sheltered) are themselves insanitary in the last degree. The greater number of the communes" (I am still quoting from official sources) "expected to carry out the provisions of the 'legge sanitaria' declare their inability to act from want of money, and in the same breath appeal for Government aid. The Government on its side pleads 'non possumus' and asserts that it does not dispose of funds to meet the prophylactic wants 'di tutto il regno' (of the whole kingdom)." It points to the melancholy and surely discreditable fact that for prophylactic purposes only 8000 lire italiane (£320) are set apart in the Ministry of the Interior—8000 lire, when the communes are 8263 in number! In these circumstances General Pelloux, as head of the Government and minister of the interior, is devising a "modo meno irrisorio" (a means less ridiculous) of fulfilling its duty to the public in the conservation of health, and to this end receives the energetic support of Dr. Baccelli, who besides being a cabinet minister is also president of the Consiglio di Sanità. *Quod felix faustumque sit!*

The Influence of Flowers on the Human Organism.

The "Bullettino della Reale Società Toscana di Orticultura," a monthly organ of fruit and flower culture published in Florence, has just brought to a close a series of interesting and instructive papers on "L'Influenza dei Fiori sull' Organismo Umano." They are from the highly competent pen of Dr. Ruggero Montelucci and will shortly see the light in an independent publication. The author's conclusions may thus be summarised: 1. That flowers not only constitute one of the best and most delicate medicaments of the excitant order (*medicamenti eccitanti*) which modern therapeutics can boast, but that, for many individuals at least, they have established a claim to be classed with those of restorative or reinvigorating media (*ricostituenti o corroboranti*), which contribute to the opportune, if temporary, rehabilitation of the organism. 2. That flowers have a distinct and potent function as purifiers of the air; that they are true and inexhaustible sources of disinfection, probably more active than the ordinary antiseptic substances; and that they operate with greater effect than may be supposed in counterbalancing the miasmata and the evil exhalations in general which are the inevitable concomitants of nature's evolution. Of special interest are Dr. Montelucci's illustrations, from experiments with flowers, of the law as stated by Dr. Mantovani of the University of Pisa in his recently published "Psicologia Fisiologica"—the law that "every pleasurable impression produces an augmentation in volume of the arm to which Mosso's 'pletismograph' is applied, together with a greater fulness in the arterial pulsations and a greater depth in the inspirations, that is to say, in the thoracic movements by which the air is admitted to the lungs."

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having previously passed the necessary examinations and having now attained the age of twenty-five years, have been admitted Fellows of the College:—

Alex. Wathen Nuthall, L.R.C.P. Lond., Mason University College, Queen's and General Hospital, Birmingham, and St. Bartholomew's Hospital; diploma of Membership dated Nov. 14th, 1895.
John Dill Russell, L.R.C.P. Lond., M.D. Lond., University College Hospital; August 4th, 1896.

The following gentlemen, having passed the necessary examinations and having conformed to the by-laws and regulations, have been admitted Members of the College:—

Rustom Pestonjee, L.M. & S. Ceylon, Exams. for L.R.C.P. Lond., of Ceylon Medical College and University College Hospital.
John Burn Wood, M.B., C.M. Edin., Exams. for L.R.C.P. Lond., of Edinburgh University.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on Monday, Oct. 10th:—

Anatomy and Physiology.—Thomas Hutchinson, Mason University College, Birmingham; John Knowles Lund, Mason University College, Birmingham and Owens College, Manchester; William Stonier Gibson, Owens College, Manchester; Charles Monks, L.R.C.S. Irel. (Surgeon-Lieutenant-Colonel, I.M.S.), Ledwich School of Medicine, Dublin; Arthur Llewellyn Baldwin Green, St. Bartholomew's Hospital and Aberdeen University; Benjamin Capon, University College, Liverpool; Joseph Ward, Firth College, Sheffield; Percy Southwell Stokes, Firth College, Sheffield, and Mr. Cooke's School of Anatomy and Physiology; Edward Postle Gwyn Causton, Cambridge University; Eugène Dunbar Townroe, St. George's Hospital; Henry Albert Ehrlich and Charles Burnage Penny, Guy's Hospital; Douglas Wilberforce Smith, Edinburgh University and Guy's Hospital; George Maw, University College, London; Bakhshi Isaac Rahim, King's College, London; Ricardo Cope, St. Bartholomew's Hospital; and Harold Edward Flint, St. Bartholomew's Hospital and Mr. Cooke's School of Anatomy and Physiology.
Anatomy only.—Roderick McKenzie Skinner, Edinburgh University; George Henry Lionel Wright, University College, Bristol; and James Wodderspoon Bennett, Owens College, Manchester, and Mr. Cooke's School of Anatomy and Physiology.
Physiology only.—John Ellington Jones, University College, Bristol.
16 gentlemen were referred in both subjects and 2 in Physiology only.

Tuesday, Oct. 11th:—

Anatomy and Physiology.—Sylvester de Carteret, Charles Louis Claude Owen, John Arthur West, Ernest Eric Young, Napoleon Leonard, and Harry Hendy Butcher, St. Bartholomew's Hospital; Hugh Frank Bodvel-Roberts, Cambridge University and St. Bartholomew's Hospital; Charles Darby Allen Dowman, St. Bartholomew's Hospital and Mr. Cooke's School of Anatomy and Physiology; Jasper Lakeman, London Hospital; Charles Henry Allen, London Hospital and Mr. Cooke's School of Anatomy and Physiology; Christopher Tredwell Holford, St. Thomas's Hospital; Lawson Jervis Hughes and William Henry Bowen, Guy's Hospital; William Wellesley Campbell, King's College, London; Henry Francis Bellamy, Charing-cross Hospital; John Evan Skey and Frank Derécourt Martyn, Westminster Hospital; William Walker Browne, Richard Ernest Lloyd, and Andrew Norris Stevens, University College, London.
16 gentlemen were referred in both subjects.

Wednesday, Oct. 12th:—

Anatomy and Physiology.—Charles Dix, Thomas Munn Body, Herbert Harland Raw, Hugh Whitwell, Ernest Walters Price, William Percival Miles, Leslie Miles Morris, and William Gerald Greaves Johnson, St. Bartholomew's Hospital; Frank Morgan, Westminster Hospital; Arthur Reginald Schofield, Robert Cecil Pitt, William MacDowall-MacDowall, and Angelo Nelson Symons, London Hospital; David Morgan Jones, St. Mungo's and Anderson's College, Glasgow, and London Hospital; Thomas Howard Frederick Roberts and William Owen Roberts, Guy's Hospital; Basil Hood, Charing-cross Hospital; Antonio Blanc, King's College, London; Bernard Moore Sampson and William Trengweath Harris, St. Thomas's Hospital; William James Deacon Inness, St. Mary's Hospital; and Arthur Watson Levy, Cambridge University and St. Mary's Hospital.
Anatomy only.—David Thomas Jones, Middlesex Hospital and Mr. Cooke's School of Anatomy and Physiology; Walter George Douglas Miller, Cambridge University and University College, London; and Campbell Tilbury Fox, University College, London.
15 gentlemen were referred in both subjects.

UNIVERSITY OF GLASGOW.—The following have passed the First Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., botany; Z., zoology; P., physics; C., chemistry):—

James Richard Sunner Anderson (P.), William Kirkpatrick Anderson (B., P.), Thomas Ballantyne (B., Z., P.), Alexander Grey Banks (B., P.), Andrew Farm Bell (B., P.), Thomas Fraser Bowie (P.), James Campbell Bringan (B., Z., C.), Robert Bruce (B.), Robert Harold Campbell (B., P.), Daniel Lyall Carmichael (C.), Alexander Adam Carruthers (P., C.), Hugh William Crawford (B., Z., P., C.), John Cross (P.), Alexander Dick (B., P.), Hugh M'Millan Donaldson (C.), Andrew Robertson Dow (P., C.), William Dow (B., C.), William Elder (C.), John Ferguson, M.A. (P., C.), Thomas Forsyth (Z., C.), John Ritchie Gilmour (P., C.), William Macmillan Gilmour (B., P.), John Miller Gordon (C.), William Harvey (B., P.), Ronald Dingwall Hodge (B. P.), John Gordon Hume (P.), John Brown Dalzell Hunter (B., P.), Neil M'Coll Hutchison (B., P., C.), Ernest David Jackson (B., Z., P., C.), William Fletcher Kay (B., P., C.), James Thompson Kelly (Z.), Alexander Dingwall Kennedy (B., P., C.), Andrew Miller Kerr (B., P.), Douglas Roberson Kerr (P.), Robert Lauder (B., C.), Robert Laurie (Z., P.), Robert Wright Leckie (B., P.), Archibald Leitch (B., P.), Stanley Everard Lewis (C.), Thomas Walker Love (B., Z., P.), Thomas Lovett (B., Z.), Joseph Paterson Lusk (B., C.), Richard Makins (Z., C.), Robert Harry Manson (P., C.), Harry Sommerville Martyn, M.A. (B., Z., P., C.), William Alexander Milne (B., C.), Alexander John Mitchell (B.), Spencer Mort (B., P.), John Bertram M'Cabe (B., Z.), James Duff M'Culloch (B., P.), Coll Macdonald (C.), Daniel Dougall M'Dougall, M.A. (Z., P., C.), Alexander Armstrong Macfarlane (B., P.), Gregor MacGregor (B., Z.), Alexander Macintyre (B., P.), John Matheson M'Kellar (B., Z.), Ivy M'Kenzie, M.A. (B., Z.), John Chancellor M'Kenzie (B., Z., P.), Thomas M'Laren (P., C.), John M'Lean (C.), Dugald Henry Macphail (B.), James Roy M'Vail (Z.), Andrew Alexander M'Whan (P., C.), James Stuart Nicolson (B., P.), David Penman (Z., C.), Thomas Rankine (B., P., C.), Andrew Reid (B., P.), John Mark Reid (B., P.), Thomas Richmond (B.), David Riddell (B., Z., P., C.), Peter Hamilton Robertson (B., P.), Robert Thin Craig Robertson (B., P.), Charles James Ross (B.), James Russell (B., C.), Lawrence Drew Shaw (B., Z., P., C.), James John Sinclair (P., C.), John Williamson Smith (B., Z., P., C.), Robert Cassels Smith (Z., P.), John Stevenson (P., C.), William David Henderson Stevenson (B.), Arthur William Sutherland (B., C.), Peter Lindsay Sutherland (B., P.), John Allan Thom (P.), John Restell Thomas (B., Z., P., C.), William Wagner Turner (B., P.), John Unsworth (B.), James Walker (B., C.), George Wallace (B., Z.), Hugh Fleming Warwick (B., C.), William Norman West Watson (B., P.), Alexander Brown Watt (Z.), and James Wilson (B., P.). *Women*—Jeanie Auld (B., Z.), Agnes Wallace Cameron (Z.), Jane Campbell (Z.), Ethel Lily Chapman (B., Z.), Ethel Macleod Lochhead (B., Z.), Jane Stark M'Lauchlan (B., Z., P., C.), Ethel Jane Mildred Pryce (B., Z.), Margaret Hossack Smart (Z., C.), Elisabeth Taylor Talbert (Z.), and Janet Gardner Waddell (Z., P.).

The following have passed the second professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (A., Anatomy; P., Physiology; M., Materia Medica and Therapeutics):—

Matthew Aikman, M.A. (A., P., M.); John Anderson (P.), George Arthur (M.), Gavin Barbour (P., M.), James Oastler Barclay (M.), Thomas Thomson Bathgate (M.), Alexander Binning (M.), Alexander Birch (P., M.), Harry Egerton Brown (M.), William Herbert Brown (M.), John Douglas Brownlie (M.), George Frederick Buchan (P., M.), Patrick Thomas Cairns (M.), Edward Provan Cathcart (M.), John Thomson Clark (P.M.), Robert Clark (M.), James Craig (P.), Charles Peter Garvie Crichton (P.), Charles Campbell Cuthbert, M.A. (M.), Gregor Hugh Grant Davis (P.), James Dick, M.A. (P., M.), Alexander Doig (A., P.), John Downie (A., P., M.), John Pinkerton Duncan, B.Sc. (M.), George Balfour Eadie (A., P., M.), Leonard Findlay (M.), John Forrest (M.), Alexander Fraser, M.A. (M.), Matthew William Fraser (P., M.), Gilbert Garrey (P., M.), David George Somerville Gartshore (P., M.), James Gemmel (A.), Edward Gillespie (M.), William Girvan (M.), Hyam Goodman, M.A. (A.), Charles Aikman Gourlay, M.A. (A., P., M.), James Dickson Gourlay (A., P.), John Gracie (P.), Charles Herbert Gunson (A., P., M.), George Pillans Harlan (M.), James Macpherson Henry (M.), Charles Milburn Hope (A., P.), Thomas Hamilton Jack (M.), John Kennedy (M.), William Bryce Kerr (M.), Alexander King (A.), James Dickson Laidlaw (A., P.), John Francis Lambie (M.), Alexander Leitch (A., P.), Norman Maclean Leys (P., M.), James Dunlop Lickley (M.), Donald M'Farlane Livingston (M.), John Lockhart (A., P., M.), Alexander Logan (M.), David Dale Logan (A., P.), David Longwill (A., P.), Jacob Mains (M.), Andrew Mair (M.), Robert MacNab Marshall (M.), Allan Martin, M.A. (M.), James Millar, M.A. (A., P., M.), Peter Moir (M.), Alexander Munro (A., P., M.), James William M'Dougall (A., P.), Walter James M'Feat (A., P.), George Steventon M'Kinnon (A., M.), James Mackinnon (M.), Burgess M'Phee (A., P.), James M'Pherson, M.A. (A., P), Duncan Mackenzie MacRae, M.A. (A., P., M.), James Patrick (A., P., M.), Peter Mackenzie Reid (P., M.), John Duncan Richmond (M.), David Russell (M.), David Shannon (P., M.), Andrew Stewart (M.), John Strathearn (A., P., M.), Robert Bryers Thom (P.), James Cameron Turnbull (M.), Albert Ernest Wainwright (M.), William Dinning Walker (A., P.), George White (A., P., M.), George Henry Wildish (P.), Thomas Watson Wilson (M.), William Webster Watt Wilson (A.), Hugh Patrick Wright (P., M.), and John Young (M.). *Women*—Auguste Boyes (A.), Gertrude Jane Campbell (M.), Helen Mary Gordon (P.), Lila Stephenson Greig (M.), Catherine Spence Howden (A., P.), Mary Emma Potter (A., P.), Mary Ann Thompson Ritchings (P.), Agnes Brymner Sinclair (P., M.), Elizabeth Helen Smith (A., P.), and Mabel Talbot (M.).

The following have passed the Third Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

James Freeborn Bennett (M.), Andrew Brownlie (P., M.), Thomas Bullough Calland (P.), James Robert Chalmers (M.), David Maclure Cowan (P., M.), John Craig (P., M.), George Morris Crawford (P., M.), William Crerar (M.), James Austin Dickie (P., M.), James

Digitized by Google

Drummond (M.), Hugh Campbell Ferguson (M.), George Gardner (P., M.), John Gardner (P., M.), William Gibson (M.), Nicol Jamieson (P., M.), Andrew Kerr (M.), Andrew Love (P., M.), Ramsay Millar (M.), Hugh Miller (M.), Ernest Wardlaw Milne (M.), Ebenezer Mitchell, M.A. (P., M.), James Hogg MacDonald (M.), Peter M'Fadyen (M.), John McGilchrist (M.), Anderson Gray M'Kendrick (P.), Charles Forbes Maclean (M.), George Todd Maclean, M.A. (P., M.), Norman Forbes MacLeod (M.), William Johnson Maclure (P., M.), Thomas Stephens Picken (P., M.), Robert Rennie (P., M.), William Alexander Riddell (M.), Arthur Robin (M.), David Ap Simon (M.), David James Smith (M.), John Steele Smith (P., M.), William Stewart Stalker (P., M.), Peter Alexander Steven (M.), Alfred George Stewart (M.), Frederic Richardson Stewart, M.A. (P., M.), Charles Pinkerton Thomson (M.), William Brown Thomson (M.), Thomas Bird Tierney (P. M.), Alexander Laurie Watson, M.A. (M.), Alexander Simpson Welle, M.A. (M.), Robert Orr Whyte, M.A. (M.), Alexander Wilson (P.), and William Wright (M.) *Women*—Sarah Davidson (P. M.), Maud Spencer (P., M.), and Edythe Marjorie Stewart Walker (P., M.).

Mr. Stewart Dunbar has passed the Third Professional Examination (regional anatomy and materia medica and pharmacy) for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.).

ROYAL UNIVERSITY OF IRELAND.—The following candidates have passed the examinations for the undermentioned degrees:—

M.B., B.Ch., B.A.O.—Upper Pass: *Edwin J. Butler, Queen's College, Cork; *Patrick Canning (M.A.), Catholic University School of Medicine; Theodore F. Dillon, Queen's College, Cork; George C. R. Harbinson and *David M'Cay, Queen's College, Belfast; Edward P. M'Loughlin (B.A.), St. Thomas's Hospital, London, and Catholic University School of Medicine; Arthur B. M'Master and Joseph Martin, Queen's College, Belfast; John Murray, Catholic University School of Medicine; Frederick S. Scott, Queen's College, Galway, and University of Edinburgh; James B. Slattery, Queen's College, Cork, and Catholic University School of Medicine. Pass: Robert A. L. Graham, B.A., and Alexander Grahame, Queen's College, Belfast; Joseph J. Hill, Queen's College, Cork; Alexander E. Knight, Queen's College, Belfast; Daniel Mahony, Catholic University School of Medicine; Robert A. Neilson, Queen's College, Galway and Belfast, and School of Medicine, Edinburgh; Henry S. Orr, Daniel S. Robinson, and Robert A. Shaw, Queen's College, Belfast; Lucy E. Smith, Queen's College, Cork; Richard B. Threlfall, Queen's College, Galway, and School of Medicine, Edinburgh; William White, Queen's College, Cork; and James E. Whyte, Queen's College, Belfast.

M.D.—Charles L. Birmingham, M.B., B.Ch., B.A.O., private study; Anna L. Church, M.B., B.Ch., B.A.O., Johns Hopkins Hospital, Baltimore, U.S.A.; and Isaac A. Davidson, B.A., M.B., B.Ch., B.A.O., Queen's College, Belfast.

* Those marked with an asterisk may present themselves for the further examination for honours.

FOREIGN UNIVERSITY INTELLIGENCE.—*Cracow:* Dr. Ludwig Switalski has qualified as *privat-docent* of Midwifery and Gynæcology.—*Gratz:* Dr. Ludwig Mark has qualified as *privat-docent* of Dermatology and Syphiligraphy.—*Lausanne:* Dr. A. Combe, *privat-docent*, has been appointed Extraordinary Professor, and Professor de Cerenville has resigned the charge of the Medical Clinic.—*Madrid:* Dr. Amalio Jimeno, of Cabañas, has been appointed Professor of General Pathology in succession to Dr. Antonio Alonso Cortés, who has resigned the chair.—*Rostock:* A special clinic is being built for ear and throat diseases near the eye clinic. It will contain 11 rooms, including wards and out-patient department, besides an operation-room and a laboratory.—*Vienna:* Dr. A. Ritter von Weismayr has been recognised as *privat-docent* of Internal Medicine; Dr. Heinrich Ludwig as *privat-docent* of Midwifery and Gynæcology; and Dr. Hans Koschier as *privat-docent* of Rhino-Laryngology. The names proposed for the chair of Experimental Pathology, vacated by the death of Dr. Stricker, are (1) Professor von Mering of Halle, (2) Professor Knoll of Prague, (3) Professor Klemensiewicz of Gratz and Professor Löwit of Innsbruck, who obtained an equal number of votes.

THE TECHNICAL EDUCATION OF PLUMBERS.—The winter session of the plumbing classes conducted by the National Registration of Plumbers in conjunction with the Perth School Board was opened on Oct. 8th in the Science Room of the Perth Academy by a lecture by Dr. John S. Lumsden. Mr. James Ramsay, chairman of the Evening Continuation Classes Committee, presided and among those present were ex-Baillie M'Neil, Mr. R. H. Miller (solicitor), Mr. Ellison (technical instructor), and Mr. William Watson. The chairman in his opening remarks said that he saw in this new departure an indication of the progress they were making in their appreciation of the value of science teaching and especially of technical instruction. After Dr. Lumsden had delivered his lecture Mr. William Watson, in the course of a few observations, said that the practical classes had for four or five years been conducted with splendid results and they now had the advantage of a teacher in the science subjects in the person of Dr. Lumsden. The chairman then presented the certificates gained last session by John Morton and David Welsh in the examination held under the graded syllabus of the Plumbers' Company.

VACCINATION GRANT.—Mr. Horace Lowther of Ventnor has been awarded the grant (sixth time) for efficient vaccination in his district.

DEATH OF MR T. H. MOXON OF YARMOUTH.—Mr. Thomas Henry Moxon, one of the oldest medical practitioners in Great Yarmouth, died at his residence, King-street, on Oct. 8th, after a short illness.

THE WINTER SESSION AT THE SANITARY INSTITUTE.—Sir Douglas Galton delivered the introductory lecture to the twenty-sixth course of lectures and practical demonstrations in sanitary science for sanitary officers and students on Oct. 17th. In the course of his address he said he would like to see sanitation made a branch of elementary education.

LITERARY INTELLIGENCE.—Messrs. Smith, Elder, and Co. will publish immediately a work upon "Albuminuria and Bright's Disease," by Dr. Tirard. The author, who assisted the late Sir George Johnson in his more recent publications on kidney disease, has treated the subject from the clinical rather than from the pathological standpoint. The book will be illustrated with 15 original plates, 4 of which, representing retinal changes in kidney disease, will be in colours.

CARDIFF INFIRMARY.—At the meeting of the Cardiff Infirmary Committee held on Oct. 12th a letter was read from Mr. Thomas Webb offering to give about £1000 for the purposes of a new and improved operation theatre in memory of his late wife. The gift was gratefully accepted and it was decided that the chairman should see Mr. Webb upon the matter. It was decided to appoint a gynæcologist. In reference to the financial position of the institution it was mentioned that the overdraft at the bank at present was £2500, and it was agreed that an effort should be made to get increased subscriptions.

UNIVERSITY OF CAMBRIDGE.—The returns from the several colleges show that 127 medical students have entered the University this term.—Dr. D. MacAlister has been appointed to act for the Regius Professor of Physic during his absence in reference to the exercises for the M.B. and M.D. degrees.—Professor Bradbury has been reappointed Assessor to the Regius Professor.—The University of Sydney is to be adopted as an affiliated university for students in arts or in science.—Professor Flinders Petrie has presented to Professor Macalister's museum 19 cases of Egyptian skulls and bones from the excavations at Hierakonopolis. They illustrate the physical anthropology of the earliest races of Egypt.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the annual meeting of the Royal College of Physicians of Ireland held on St. Luke's Day the following officers were elected for the ensuing year. President: Dr. John William Moore. Vice-President: Dr. W. J. Smyly. Censors: Dr. W. J. Smyly, Dr. H. C. Drury, Mr. J. Murphy, and Dr. A. K. F. McCutcheon. Additional examiners to take the place of an absent Censor:—Medicine: Mr. W. L. Symes. Medical Jurisprudence and Hygiene: Mr. A. N. Montgomery. Midwifery: Mr. T. H. Wilson. Examiners for the Licence in Midwifery: Mr. Andrew J. Horne and Mr. E. Hastings Tweedy. Additional examiners under the Conjoint Examination Scheme:—Biology: Dr. E. MacDowel Cosgrave. Chemistry and Physics: Dr. H. T. Bewley and Mr. Edwin Lapper. Materia Medica and Pharmacy: Dr. F. J. B. Quinlan and Dr. Ninian Falkiner. Physiology: Dr. J. Mallet Purser. Pathology: Dr. Wallace Beatty. Medicine: Dr. H. C. Tweedy and Mr. E. E. Lennon. Hygiene and Forensic Medicine: Mr. S. T. Gordon. College Examiners for the Conjoint Diploma in Public Health:—Meteorology: Dr. Ninian Falkiner. Hygiene: Dr. F. J. B. Quinlan. Chemistry: Mr. Edwin Lapper. Examiners in Preliminary Education: Mr. William Kennedy, B.A., Sch. T.C.D. Science: Mr. C. Joly, F.T.C.D. Representative on the General Medical Council: Dr. Lombe Atthill. Representatives on the Committee of Management under the Conjoint Examination Scheme: Dr. John Magee Finny, Sir Christopher J. Nixon, and Dr. James Craig.

Digitized by Google

Treasurer: Dr. Lombe Atthill. Registrar: Dr. James Craig. In the evening the annual banquet of the President and Fellows was held in the College Hall.

KING'S COLLEGE, LONDON.—The following scholarships in the medical school have been awarded. Medical Entrance (Universities) Exhibition: 70 guineas Charles Harrison Barber; and 60 guineas, Herbert S. Flook. Warneford Entrance Scholarships (Arts): £25 a year for two years, Thomas Henry Jones; and £25 a year for two years, John James and Eardly Lancelot Holland (equal). Sambrooke Medical Exhibition (Science): £60, Albert Angelo Myers; and £40, Harold Benjamin Day. Rabbeth Medical Scholarship (Science): £20, Harold Benjamin Day and Albert Angelo Myers (equal). The Clothworkers Science Exhibitions (open to all Faculties of the College); £30 a year for two years, Arthur Wright; and £20 a year for two years, William Marden.

VACCINATION EXEMPTION CERTIFICATES.—At the Llandaff, Glamorganshire, police court on Oct. 10th a man applied for a certificate of exemption under the Vaccination Act. He was about to be sworn when the presiding magistrate (Mr. E. W. David) interposed and said that he refused to adjudicate in future on vaccination cases, for he would not be responsible for the scourge which will inevitably overtake this country if this Act remains in force. Colonel Fisher said he endorsed in the main the remarks of his colleague and the application was not granted.—At the meeting of the Monmouthshire Joint Committee at Newport on Oct. 12th during a discussion upon vaccination exemption certificates Colonel Lyne remarked that the new Vaccination Act was a difficult and even obnoxious Act, but there ought to be uniformity in its administration.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The usual quarterly court of the directors of this society was held on Oct. 12th, Dr. Pollock, Vice-President, being in the chair. Two new members were elected. No deaths of members were reported. Applications for relief were read from 49 widows, 11 orphans, and 6 recipients from the Copeland Fund, and it was resolved that £1197 11*s.* be distributed amongst them at the next court. There were no fresh applications for grants and one orphan had become through age ineligible for further assistance. The audited accounts of the last half-year were read and it was resolved to apply the surplus to giving a Christmas present to the 49 widows, 12 orphans, and 5 recipients from the Copeland Fund—viz., £10 to each widow, £3 to each orphan, and £5 to each of those receiving assistance from the Copeland Fund; in all £551. The expenses of the quarter were £64 1*s.* 6*d.*

FREEMASONRY.—*The Æsculapius Lodge, No. 2410:* The seventh installation meeting of this Lodge was held at the Café Royal, Regent-street, on Oct. 12th. Bro. H. W. Kiallmark, M.R.C.S. Eng., was installed master for the ensuing year by Bro. E. H. Ezard, M.D. Edin. The occasion was an eventful one, as Bro. Kiallmark is also a Grand Officer for the year, having had the collar of G.J.D. conferred upon him by the Grand Master H.R.H. the Prince of Wales. Bro. G. Danford Thomas, M.D. Brux., coroner for Central London, was re-elected treasurer, and Bro. Thomas Dutton, M.D. Durh., secretary. Bro. Eyre, M.D. Durh., was admitted to the third degree, and Bros. Pakes and Eaton to the second degree. There was a large number of visitors present, including Bros. Ralph Gooding, M.D., P.G.D., Clement Godson, M.D. Aberd., P.G.D., Inspector-General Belgrave Ninnis, M.D. St. And., R.N., P.G., Std. Br. The members and visitors afterwards dined together and spent a very enjoyable social evening.

THE LATE MR. COTTLE OF CHELTENHAM.—The death has been announced of Mr. J. T. Cottle, which took place on Oct. 12th at Pulteney-villa, Winchcomb-street, in his eighty-eighth year. The deceased gentleman was one of the oldest—if not the oldest—medical practitioners in Cheltenham, and his long connexion with the town won him universal respect. For some time past he had been in failing health, though he carried his years well. He was one of the oldest Poor-law officers in the country, and in 1848 was appointed a permanent medical officer of the union. In 1867 he was given the office of honorary surgeon to the 10th Rifle Volunteers and retained a similar position in the 2nd Volunteer Battalion Gloucester Regiment to his death. He was one of the promoters of Cheltenham College. He was an ardent sportsman and he kept greyhounds for about thirty years and took a keen interest in the Waterloo Cup competitions, dividing the Champion Stakes at Altcar in 1889. He was twice married; his second wife died a few years since while on the way to the West Indies on the honeymoon. The shock to Mr. Cottle was necessarily severe and it told somewhat on his health.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ALEXANDER, G. P., F.R.C.S. Edin., L.F.P.S. Glasg., has been re-appointed a Medical Officer for the Forfar Infirmary.

ALLFREY, FRED. H., B.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Physician to the Royal Free Hospital, Gray's-inn-road.

CABLE, J., L.R.C.P. Edin., L.F.P.S. Glasg., has been re-appointed a Medical Officer for the Forfar Infirmary.

CHINERY, E. F., L.R.C.P., F.R.C.S. Edin., M.R.C.S., has been re-appointed a Medical Officer for the New Forest Union.

COLLIER, R. S., L.R.C.P. Lond., M.R.C.S., has been appointed a House Surgeon for the North Riding Infirmary, Middlesbrough.

ESKRIGGE, R. B., L.R.C.P. Edin., M.R.C.S., has been appointed a Medical Officer of Health by the Royston Urban District Council.

COWPER.—On Oct. 12th, at Havelock, Shanklin, I.W., the wife of John Cowper, M.B., of a son.

FARR.—On Oct. 10th, at St. Helier's, Ealing, W., the wife of Ernest Farr, M.R.C.S., L.S.A., of a daughter.

KIDD.—On Oct. 13th, at Rosslyn-gardens, Hampstead, the wife of Leonard Kidd, M.D., of a daughter.

KOETTLITZ.—On Oct. 16th, at Pencester-road, Dover, the wife of Maurice Koettlitz, L.R.C.P. Lond., of a daughter.

LIPSCOMB.—On Oct. 15th, at Starcross, Devon, the wife of Edgar R. S. Lipscomb, L.R.C.P. Lond., M.R.C.S., L.S.A., of a son.

MARRIAGES.

CATO—SHORT.—On Oct. 18th, at St. John the Evangelist's, Ponge, Alexander McLean, M.R.C.S., L.R.C.P., eldest son of William Robert Cato, of Anerley, to Katharine, third daughter of the late Thomas Short, of Carlisle.

CORNER—DRAKE.—On Oct. 18th, at Trinity Church, Walthamstow, Albert Corner, of Forest-gate, M.R.C.S. and L.R.C.P., to Nellie, second daughter of W. J. S. Drake, Forest-gate.

CREAK—CROCKETT.—On Oct. 12th, at St. James's, Kidbrooke, Alexander Brodie Creak, M.R.C.S., L.R.C.P., second son of Captain Creak, R.N., of Blackheath, to Mary Frances, elder daughter of Edwin A. B. Crockett, of Ashley-gardens, S.W.

DEATH.

COTTLE.—On Oct. 12th, at Pulteney Villa, Cheltenham, Thomas James Cottle, M.R.C.S., in his 88th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat Hospital (2 P.M.).

TUESDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.), Royal Ear Hospital (3 P.M.).

WEDNESDAY (26th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

THURSDAY (27th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.).

FRIDAY (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (29th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (24th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Sheild: Four Cases of Abdominal Section for Severe Injuries without External Wound.—Dr. F. L. Benham: On the Advantage of Venesection in Acute Pneumonia, with cases in illustration.

TUESDAY (25th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. H. L. Lack (communicated by Dr. A. Macfadyen): Fibrinous or Membranous Rhinitis and its Relation to Diphtheria.—Dr. E. Cautley: Congenital Hypertrophic Stenosis of the Pylorus.

WEDNESDAY (26th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus).—8.30 P.M. Clinical Evening. Cases will be shown by Dr. F. J. Smith, Dr. Chaplin, Dr. J. H. Sequeira, Mr. Tubby, and other Fellows of the Society.

THURSDAY (27th).—NEUROLOGICAL SOCIETY OF LONDON (Medical Society's Rooms, 11, Chandos-street, W.).—8.30 P.M. Dr. Ormerod and Dr. Batten: Idiopathic Muscular Atrophy (Landouzy-Déjerine type) in Mother and Son.—Dr. Beevor: Unilateral Wasting and Paralysis of Lower Half of Trapezius.—Dr. Mott: Arsenical Neuritis from Local Action of the Poison, followed by General Degeneration Effects upon the Nervous System.—Dr. Ormerod: Case of Hereditary Chorea.—Mr. Lake and Mr. Ballance: Case of Recovery from Temporo-sphenoidal Abscess.—Dr. Beevor and Mr. Ballance: Case of Removal of Subcortical Cerebral Tumour.—Dr. J. Taylor and Mr. Ballance: Case of Trigeminal Neuralgia successfully treated by Krause's Operation.—Dr. Lunn and Mr. Ballance: Case of Removal of Cerebellar Tumour three years and eleven months after the operation.

FRIDAY (28th).—CHARITY ORGANISATION SOCIETY (Portman Rooms, Baker-street, W.).—4.30 P.M. Dr. L. A. Hawkes: The Dispensary. (Course of Lectures on Medical Relief.)

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11, Chandos-street, Cavendish-square, W.).—3 P.M. Dr. M. Hunt (President): Inaugural Address. Cases will be shown by Dr. D. Grant, Dr. Milligan, Dr. Lamb, Mr. Lennox Browne, Mr. W. Wingrave, Dr. F. Potter and others.

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Clinical Evening. The following cases will be shown:—Dr. W. S. Colman: Syringo-myelia.—Mr. J. Clarke: Rachitis Adolescentium.—Dr. N. Dalton: Double Athetosis in a Boy.—Mr. Watson Cheyne: Repair of the Bridge of the Nose by Rabbit Bone.—Dr. S. Phillips: A Case of Chyluria.—Mr. Page: Ankylosis of Lower Jaw treated by Removal of a Wedge from the Neck. And other cases. Patients will be in attendance at 8 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (24th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. G. Stoker: Chronic Glandular Disease of the Nose and Naso-Pharynx.

TUESDAY (25th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, W.C.).—3.30 P.M. Dr. Ferrier: Hemiplegia.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. P. Abraham: Psoriasis.—Bethlem Hospital, 2 P.M., Dr. Craig: Stupor; Katatonia; Dementia and Senile Insanity.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—4 P.M. Dr. T. D. Savill: Cases illustrating the Different Forms of Hysterical Attack, their Pathology and Treatment.

WEDNESDAY (26th).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: House Drainage.

Digitized by Google

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Habershon: Bronchiectasis.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Bidwell: The Application of Plaster-of-Paris and other Splints.

THURSDAY (27th). — LONDON POST-GRADUATE COURSE. — Central London Sick Asylum Cleveland-st., W., 5.30 P.M., Dr. Mitchell Bruce: Clinical Lecture.
THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Barlow.
CHARING-CROSS HOSPITAL.—4 P.M. Dr. Galloway: Dermatological Demonstration. (Post-Graduate Class.)
THE LONDON SKIN HOSPITAL (40, Fitzroy-square, W.).—4 P.M. Mr. J. Startin: On Gouty Eczema.

FRIDAY (28th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Anthrax and Malignant Œdema.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Cheatle: The Application of Splints to the Lower Extremity.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—The following question has been asked me; perhaps some of your readers will kindly give an answer. X is a growing spa. In it are already settled four medical practitioners. Would it be ethically wrong for another medical man to settle in the place or to go thither three or four days in the week for consultant practice?

I am, Sirs, yours faithfully,
Oct. 18th, 1898. M.D.

WHAT CONSTITUTES A PARTNERSHIP?

To the Editors of THE LANCET.

SIRS,—A and B are in partnership, having equal shares in a practice. Twelve months ago C goes to them as an out-door assistant at a fixed salary. At the expiration of six months A and B offer C a partnership in lieu of the assistantship, C to receive a fifth share of the nett profits in lieu of salary and A and B two-fifths each. C accepts the offer and his name thereupon appears on the surgery door and on the billheads as a member of the firm, besides which A and B repeatedly inform the patients that C is their partner and *not* the assistant. A deed is drawn up by one of the partners, but C and the other partner objecting to the wording of one of the clauses the deed is not signed but remains in the possession of C awaiting rectification. In the meantime, however, C receives his fifth share of the nett receipts which are divided up weekly, A and B receiving their two-fifths each. This goes on for six months when A and B inform C that the practice is too small for three partners and as no deed had been signed C must regard himself as only occupying the position of assistant and as subject to a month's notice. C declines to accept the notice on the ground that his name having appeared on the business premises and on the stationery and having been the recipient for six months of a weekly share of the profits he is a *bonâ fide* partner, notwithstanding the fact of there being no deed of partnership. Is C right in his contention that the facts as herein stated constitute a partnership? and is he justified in refusing to go out of the firm? The usual assistant's bond which C signed on first going to A and B is still in their possession. Is it still binding on C or should it have been destroyed when C became a partner? If taken into court neither A nor B could state on oath that they had not regarded C as their partner.

I am, Sirs, yours faithfully,
Oct. 19th, 1898. A READER.

*** It seems clear from the above *ex-parte* statement that A and B have made C a partner and have treated him as such. They cannot therefore relegate him to the position of an assistant without his sanction. The bond should have been formally cancelled when C ceased to be an assistant. Only a solicitor with the draft agreement and the bond before him could decide accurately what is C's best legal course. The matter is exactly one for friendly arbitration.—ED. L.

"VULGAR METHODS": AN EXPLANATION.

To the Editors of THE LANCET.

SIRS,—My attention has been directed to THE LANCET of Sept. 24th, in which you print a series of labels. The red labels which you so forcibly impress were evidently disseminated by my locum tenents during my absence from home.

I am, Sirs, yours faithfully,
Plashet-grove, East Ham, Oct. 18th, 1898. HY. HUTCHINSON.

"ADVERTISING."

To the Editors of THE LANCET.

SIRS,—I have received a copy of your journal, dated 15th inst., containing an announcement headed "Advertising" in connexion with my name. That announcement exposes me to an odium that, as I think, I do not in any degree deserve. I was obliged to change my address under very exceptionable and pressing circumstances through no fault of my own, and I did not intentionally send the card in question to anybody to whom I did not believe myself entitled conformably with professional usage to give notice of my removal. In fact, I scrupulously followed the course recommended to me by one who informed me that he had himself followed that course in all its details under similar circumstances on behalf and under the direction of a leading consultant now deceased. Moreover the card sent out for me was copied from the card sent out for that consultant and engraved at the same engraver's. I do not consider that anything I have knowingly done rightly exposes me to any censure that would not be quite as applicable to the eminent consultant above referred to, and he certainly was one whose judgment on a point of professional etiquette could not have been lightly challenged, nor was he by any means singular in his views and conduct in such matters.

I regret, as regards the addressing, &c., of the envelope, that through an oversight any annoyance should have been given to your correspondent.

I am, Sirs, yours faithfully,
Gloucester-place, Portman-square, W. W. BURSLEM ROTHEROE.

INNSBRUCK AS A WINTER RESORT.

MR. W. BUCHANAN, M.R.C.S. Eng., of Chatham, writes to us drawing attention to the claims of Innsbruck as a winter resort. Innsbruck lies at an altitude of 1912 ft. above the sea in a sheltered valley. It is blessed with an abundant supply of pure water brought down from the mountains, a most important item, and owing to the nature of the soil the ground dries very quickly after rain. The weather during November, December, January, and February is dry, still, and cold, with a bright sun, blue sky, and hard dry snow on the ground.

THE PROHIBITION OF CORSETS IN RUSSIAN SCHOOLS.

To the Editors of THE LANCET.

SIRS,—The Russian Minister of Education has forbidden the wearing of stays by the female students under his jurisdiction. Presumably, the reason for this edict is a laudable desire that the Russian educated woman shall rejoice in a natural waist. Regulations dealing with dress, especially with such garments as do not meet the eye, are difficult to enforce and easy to evade; but apart from the difficulty of making such rules effectual it is questionable whether the absolute banishment of every kind of corset would be advantageous. The wasp-waist which has for centuries deformed our female ancestors, though it dies hard, is undoubtedly on its death-bed. Perhaps the case is different in Russia, but among English-speaking women active exercise and games out of doors have become almost universal during the last few years and have necessitated a mode of dress which, while leaving something still to be desired, is on the whole sensible and rational. The corset has shared in the improvements and modifications which are found in every article of attire; there need now be no difficulty in procuring a garment which, without producing any compression or deformity, will nevertheless give to the wearer just the amount of support required by modern dress. The flowing robes of the Greeks needed no such support. But in these days the flowing style would be an inconvenient one to adopt; most women wearing modern dress, excepting the very thin and slight, feel more comfortable in stays of some sort. Many stays are made with shoulder straps and arrangements for attaching the underskirt and stocking suspenders, thus doing away with garters, bands, and strings, and allowing the clothing to be suspended from the shoulders instead of dragging on the hips; such stays have soft

Digitized by Google

flexible "bones," yielding to every movement of the body and easily withdrawn for laundry purposes. They serve two purposes, supporting the figure and affording a comfortable means of attachment for the other underclothes. Such garments need not be tight; they answer best and are most comfortable when fitting properly and allowing due expansion of the chest and abdomen during breathing. To prohibit their use would be to deprive their wearer of a comfortable and rational garment. The Russian Minister of Education would be only logical were he to forbid men and women alike to wear boots and shoes because certain people have in times past constricted and deformed their feet.

I am, Sirs, yours faithfully,

Clapham-common, S.W., Oct. 17th, 1898. D. CAINE, M.D.

THE POSITION OF THE ASSISTANT WITH REGARD TO FEES EARNED AT CORONERS' INQUESTS.

"A is assistant to B on a salary with a commission on midwifery receipts. He is called in to see a patient and finds him dead on his arrival. Subsequently he makes a post-mortem examination, giving evidence before the coroner. Is he entitled to any part of the fee thus earned in the absence of any agreement to the contrary?"—The gentleman who sends this question to us informs us that A and B feel quite amicably towards each other and does not inform us if he is A or B. The fees belong legally to A, but it is the habit of many principals—and we think a graceful and right habit—to divide such fees with the assistant when all the labour and responsibility has fallen upon the assistant.

"POWDER PUFFING": AN EXPLANATION.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to an observation in THE LANCET of Oct. 15th in which it is stated that the wrapper of a certain baking powder has upon it a testimonial signed by me. In reply I wish to remark that in the course of seventeen years' service as medical officer of health I have had to do some analytical work and that occasionally during the same period articles of a dietetic or other nature have been submitted to me by various people for qualitative analysis, several baking powders being amongst the number. As I have usually given a certificate as to purity, &c., I take it that the wrapper in question bore a copy of such a certificate. This does not appear to me to be "powder puffing"; neither have I lent my name for use in connexion with this or any other article. I am not aware therefore that I have infringed any Act of Parliament or by-law of the General Medical Council by giving such a certificate to any person who has considered my analytical report worth seeking. Numbers of medical men give such; hundreds are given every year. Trusting that you will give this explanation the same prominence in your valuable paper that you did the observation referred to.

I remain, Sirs, yours faithfully,

Nottingham, Oct. 15th, 1898. WILLIAM TIBBLES.

*** We publish the explanation with pleasure.—ED. L.

THE COUNTERFEITING OF ANCIENT COINS.

A WRITER in the *Revue Scientifique* of Oct. 15th states that the Italian manufacturers of coins and medals intended to be sold as ancient have a strange method of giving them the "patina" or superficial oxidation which is supposed to be characteristic of genuine antiques. Large birds, such as turkeys, are made to swallow imitation coins of the Roman emperors, and if the coins when voided do not present the desired appearance they are repeatedly subjected to the same process. The inference is that the effect is due to the action of the intestinal juices and gases.

MEDICAL OFFICERSHIPS IN THE HIGHLANDS AND ISLANDS.

To the Editors of THE LANCET.

SIRS,—Owing to the number of these vacant posts appearing in the "dailies" at present and the harsh treatment often meted out to the unfortunate young gentlemen who accept them you could not do better than direct your readers before accepting such places, particularly Skye and Orkney, to address the last medical officer for an honest opinion of their value and treatment to be expected.

I am, Sirs, yours faithfully,

Oct. 17th, 1898. JOHN TAYLOR, M.D.

THE POPULATION QUESTION IN FRANCE.

ACCORDING to *La Science Française*, there are 8,713,266 families in France with one or more living children, the number in each family being as follows. In 2,640,894 families, or 30·3 per cent. of the whole, there is only 1 child; in 2,364,202, or 27·1 per cent., there are 2 children; in 1,585,960, or 18·2 per cent., 3 children; in 975,616, or 11·2 per cent., 4 children; in 572,285, or 6·5 per cent., 5 children; in 322,651, or 3·7 per cent., 6 children; and, finally, in 251,658, or 2·9 per cent., there are 7 or more children. It is evident, says the writer, that in the matter of posterity the French nation cannot hope to establish a record. In a scientific journal one naturally looks for accuracy, but if the above figures are to be accepted, the population of France, exclusive of barren families and also apparently of single men and women, exceeds 40,000,000. Writing in *La Médecine Moderne* on what he calls "la Veulerie contemporaine," Dr. Fiessinger describes a "moral malady," which may or may not be accountable for the paucity of children in French households. "A social epidemic," he says, "has cast its net over the different classes; sparing none, collecting them all into one great flock, where they remain dumb and bereft of ambition. It is the leading vital question of the day this utter absence in modern society of energy, this lack of all initiative. The foundations of the State must be assured, the public equilibrium must be maintained at any cost. Hence the suppression of individuality, the levelling down of temperament, the crushing of aspiring spirits beneath the roller of uniformity additionally weighted by suspicion and jealousy. Such is the ideal to be attained to, the sublime crown which has to be wrought. Collectivism cannot endure that aught should emerge above the dead level of equality. Its favours are reserved for those who can stoop down to the official standard. Universal mediocrity; such is the dream of the collectivist." Frenchmen would seem to be afraid of large families because in their opinion all the children have to be provided for alike. They have no approval of the law of primogeniture.

THE CLIMATE OF THE DISTRICT AROUND JOHANNESBURG.

A CORRESPONDENT would be very grateful if anyone could tell him from personal knowledge some facts about the climate of the districts lying round Johannesburg. He is desirous of avoiding dust-storms.

M.R.C.S.—Seven teeth defective or deficient in persons under seventeen years of age on the day of entry or ten defective or deficient teeth in persons above the age of seventeen years disqualify. No departure from this rule is permitted without special authority from the Admiralty. Both classes of persons must, however, possess at least four perfectly sound opposing molars—viz., two in each jaw, and the same number of incisors similarly placed. A tooth is to be considered as defective when it cannot be made permanently serviceable by dental repair. In all cases due regard is to be paid to the condition of the remaining teeth and the probability of their lasting for at least twelve years. Credit is to be given for teeth which have not erupted, unerupted wisdom teeth excepted.

Registered Medical Student cannot take fees for attendance upon midwifery cases, and there is no "institution" which can give him the legal right to do so except such bodies as can transform him—after examination—into a qualified and registered medical man. Any medical man employing a student to attend midwifery cases for him would be liable to censure or worse from the General Medical Council, whose recent pronouncement about unqualified assistants seems to have escaped our correspondent's notice.

A Father of Nine.—We cannot publish a letter inviting suggestions for medical treatment and we do not give medical advice ourselves. Recourse must be had to the family medical man.

Enquirer.—We see no reason for believing that the medical men were privy to the insertion of the paragraph.

Mr. J. Williams.—We do not know of any work treating the subject named.

METEOROLOGICAL READINGS.

An Address

ON

THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

Delivered at the Technical College, Huddersfield, on Oct. 22nd, 1898,

BY SIR WILLIAM BROADBENT, BART., M.D., F.R.C.P. LOND., F.R.S.,

CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL.

GENTLEMEN,—Having been called to Huddersfield on one matter concerning the public health it occurred to me that I might perhaps render a service to my native town and neighbourhood by bringing before you another question of great importance—namely, the prevention of consumption. I claim no special knowledge of the subject and shall have nothing to say which will be new to my medical friends in Huddersfield, so many of whom I see around me to my great satisfaction, and I should like to begin my lecture here by thanking heartily the members of the profession, and particularly Mr. Knaggs, for the cordial support and encouragement they have given me in this matter. You would have learnt from them in course of time how the ravages of tubercle may be stayed, but knowledge percolates slowly, and while it was being brought home to the general public many hundreds of valuable lives might be sacrificed. It is the realisation of this fact which has led to the formation of the National Society for the Prevention of Consumption and Other Forms of Tuberculosis.

You are all familiar with the prevalence of consumption. There can scarcely be a person here who has not lost some relative or friend from this disease. Statistics, therefore, are scarcely necessary, but it will perhaps bring more definitely before your minds the serious loss of life to which tuberculous disease gives rise in this neighbourhood if I quote the figures relating to it which are found in the able report of Mr. Annis, your medical officer of health, for the year 1897, and show you on an enlarged scale a diagram which he has made illustrating the proportion of deaths from all causes. You will see what an enormous preponderance consumption claims. The total number of deaths in the borough in 1897 was 1666, and of these 222, 1 in 7·5, were due to the various forms of tuberculous disease. We are, say, 800 people in this room; 80 or 100 of us will die from consumption or other effect of tuberculosis. You will all agree that if this terrible sacrifice of life is preventable it ought to be prevented. I can imagine some of you who are cynically minded, and especially such as consider themselves safe from diseases of this kind, saying, "Well, we must die from something; why not from phthisis?" If consumption only weeded out the weaklings there might be something in this view of the matter. But it is often the most gifted, the most useful, the most diligent, the most intelligent, the most amiable who are carried off in this way. Is this not so? And then it is so tedious and trying and often so painful and distressing a way of leaving the world; and so expensive too, frequently exhausting the entire resources of a family.

Until the last few years the idea was that consumption was a disease which was in the family, a constitutional tendency which could only be accounted for by heredity and against which it was in vain to strive, an inevitable evil to be submitted to as a decree of inscrutable providence. Added to this was the impression that it was incurable, and thus efforts to relieve and cure it were paralysed. But these ideas, I am thankful to say, are wrong. Tubercle is not inherent in the constitution. Consumption is not an inevitable disaster, inflicted by a mysterious fate; it is, on the contrary, one of the products of men's ignorance and carelessness. We now know how it is brought about and it is within the power of man to prevent it. Consumption is "caught," to use a familiar expression, from a pre-existing case; not, let me add at once, communicated directly from person to person by breathing the same air or even sleeping in the same room. There is no need to aggravate the sufferings of the phthisical patient by treating him as a public danger; no need to drive wife or child out of the house to save the rest of the family. The agent in the causation and transmission of the disease is the tubercle bacillus, a minute rod-like organism, which multiplies at an amazing rate. It is visible only under very high powers of the microscope and then only after careful straining. A favourite subject of discussion at one time was how many angels could stand on the point of a needle. Well, hundreds of these little demons could be carried on the point of a needle The bacilli then obtain access to the lungs or to other organs and if they find the soil suitable, and if they are not destroyed by the defensive agencies which are happily present in the system, they proceed to increase and multiply, compressing and blocking the minute blood-vessels and lymphatics, choking the air passages and air vesicles of the lungs, and forming the little pin-head solid bodies which gave rise to the name tubercle. Eventually the nutrition of the structures is so interfered with that they lose their vitality; inflammation is set up and the result is that the tubercles and the portion of tissue invaded by them soften and break down, forming small cavities which extend and coalesce till cavities of considerable size result. This is not the only harm they do, for besides damaging and destroying the tissues they form a poison or toxin which is absorbed into the blood, and by its presence in the circulation gives rise to the fever, sweating, and wasting which attend consumption.

We should naturally suppose that these tubercle bacilli being present in diseased lungs by millions would be carried out by the breath, but this is not so. They are not found in the moisture condensed from the breath, or on a piece of cold glass or metal, or in fluids through which expired air is made to pass. But they are contained in countless numbers in the expectoration and become the means by which the disease is disseminated. These bacilli are possessed of extraordinary vitality, even outside the body, but there are certain agencies which they cannot resist—heat, sunlight, and fresh air. Fresh air and sunlight are, in fact, the great enemies of all pathogenic organisms. The drying of the expectoration, however, does not kill the tubercle bacillus. Apparently, on the contrary, the desiccated organic matter serves as a protection to the bacilli, so that in the form of dust they survive indefinitely. The expectoration, then, of a consumptive person upon a pocket-handkerchief, or accidentally contaminating articles of dress or the carpets of a room, may sooner or later take the form of dust and so be carried about in the atmosphere. But careless people will spit about in the streets and roads and when not under observation in railway carriages and other public conveyances, in public buildings, especially in the corridors and passages, perhaps even in churches or chapels. This is not only nasty but dangerous. There is always the possibility that it may get dried, perhaps on ladies' dresses, which it contaminates, and be dispersed as dust, and it is by the inhalation of germ-laden dust that the seeds of phthisis are planted in the lungs.

We do not realise how ubiquitous dust is. We scarcely know where it can come from when we see it lying on papers, furniture, picture frames, windows, and in the holes and corners into which the diligent housemaid pursues it. You have all seen the motes dancing in the sunbeams crossing the room; you may have seen them in the rays of the lamp this evening. Every mote is a dust particle which may carry on its person numbers of tubercle bacilli. This is how consumption is usually contracted. In every breath we take we inhale an incalculable number of motes or dust of a more palpable form. Some of these may elude the defences which nature has planted in the respiratory passages, the filtering arrangement in the nose for entangling and arresting microbes, and the cilia of the windpipe and bronchial tubes, and reach the air cells. Then, if the local and constitutional conditions favour the development of the bacilli, the mischief is done. Let one bacillus out of a million find its way to predisposed lungs and consumption will be rife.

But there is another way in which tuberculosis is disseminated and that is by means of milk. Cows are very subject to tuberculosis, and at a certain stage of the disease tubercle bacilli are present in the milk. It is through milk so contaminated that children come to have tuberculous disease, tabes mesenterica, tuberculous disease of the bowels and mesenteric glands (better known, perhaps, as consumption of the bowels), and, directly or indirectly, tuberculous meningitis, or inflammation of the brain, or acute hydrocephalus. The disease of bones and joints to which children are

Digitized by Google

subject are probably also traceable to milk; humpback, hip-joint disease, and the diseases of knees, elbows, &c., which cripple so many children; perhaps so is lupus; and no doubt tubercle is often implanted by milk in early life which develops later into consumption. While blaming the cows we must not forget that a consumptive mother may not only be wasting her own strength by suckling her child, but may be sowing in it the seeds of some of these diseases.

It is interesting to note that asses and goats do not suffer from tuberculosis and to bear in mind that the shrewd physicians of past days used to order asses and goats' milk for persons threatened with consumption. You will see how necessary it is that the milk-supply of large towns should be guarded from tuberculous contamination, and I am glad to find that the health authorities of Huddersfield are fully alive to this. The regulations with regard to cowsheds, dairies, and milk-shops on pages 39 to 44 of the medical officer's report for 1897 are admirable. They may be read with advantage by all consumers of milk and by those who keep cows for the supply of milk to their own households. I should like to see the medical officer of health empowered to make an addition, viz., that no person suffering from phthisis should be employed about cows. Consumptive persons should especially be forbidden to engage in milking or in the handling or distributing of milk. I do not like to contemplate the disgusting possibility of contamination of milk by sputa, but we cannot but admit that it might occur. There is no need to consider at any lengh the contingency of the communication of tuberculous disease by means of meat. This is adequately provided against by the public slaughter-house and by the careful inspection of meat. You are all the more secure in Huddersfield in consequence of the excellent relations which exist between your medical officer of health and the butchers of the town. Besides we do not eat our meat raw, and cooking is fatal to bacilli. The measures which are required for the prevention of consumption are at once suggested by what I have said as to the methods by which it is disseminated, but before entering upon these I must say a few words with regard to the old idea as to family proclivity and hereditary tendency to consumption. This was not a mere theoretical assumption; it was based on observed facts, and nothing could be more foolish than to reject a conclusion founded on experience simply because the explanation was erroneous.

Although the immediate cause of consumption is the implantation of the tubercle bacillus, it is still perfectly true that consumption runs in certain families and that constitutional predisposition is an important factor in the production of the disease. But it is not actual disease which is transmitted from parent to child, nor will any degree of tendency in the constitution induce it. The hereditary constitutional predisposition is simply a liability to tuberculous disease on exposure to the germs, a vulnerability of the tissues producing a suitability of soil. Two people may be equally exposed to invasion by the bacilli and one will develop phthisis while the other will not, and we can usually tell beforehand which of the two will succumb and which resist. It may be mentioned that gout seems to reinforce the resistance to infection by tubercle, and, curiously enough, so does the anæmia to which young girls are subject. Besides, however, a constitutional susceptibility, another reason why consumption prevails in certain families is that generation after generation live under the same unfavourable conditions in dark, damp, ill-ventilated houses—in houses very often which actually harbour the bacilli left by previous cases.

As regards the preventive measures which must be adopted I will first complete what I have already said on this point as to milk. To begin with, an absolute defence against the communication of tubercle bacilli by means of milk is to boil it. But some people, children especially, do not like boiled milk or think it does not agree with them. But the desired end, the destruction of the bacilli, can be attained by exposure for a certain time to heat short of the boiling point—by sterilisation as it is called. This, however, demands a little time and trouble, and in how many households is the simple boiling of the milk too great a trouble? Fortunately, milk is now sterilised on a large scale at many of the more important dairies and can be supplied in any quantity. As it keeps indefinitely while the bottles are sealed it can also be sent to any distance. I tasted some at the Sudbury Dairy on Lord Vernon's estate a few weeks ago which was a month old and as fresh and sweet as on the day it was milked. The railway companies ought to insist on this sterilised milk being kept at refreshment rooms instead of the tumblers of milk which we see exposed on the counter—which may have been standing there for half a day, absorbing bacteria and filthy emanations of every sort. If the railway company do not insist on it in defence of their passengers I hope the public will do it in self-defence. It is to the defensive instincts of the public that we appeal. But while we can kill the bacilli in milk we have a right to demand that milk shall be supplied to us which does not contain them. This opens up a large subject. An enormous proportion of the milch cows in this country and over most of the continent is affected with tuberculosis and they are potential sources of disease. Contrary to one's expectations, tuberculosis is much less prevalent among cows kept for dairy purposes in large towns than in the herds of dairy farms. This is due to the fact that cows which come under the purview of the medical officer of health are inspected and perhaps tested and such as are diseased are killed off or quickly got rid of in some way. It is a melancholy thing that the greatest danger comes from fresh country milk. It is with great reluctance that I contemplate the imposition of a new burden on the distressed agriculturist, but pure milk we must have. Fortunately, an easy and certain test for the presence of tuberculous disease in the cow exists in the subcutaneous injection of tuberculin, and already in many herds animals found to be affected are separated from the rest and gradually got rid of. In a few years with precautions against the introduction of new animals affected with tuberculosis the disease can be eradicated. This is a matter for rural and district councils and for land-owners. It has, in fact, been taken up by far-sighted and public-spirited landlords, and the Minister of Agriculture, the Right Hon. Walter Long, has given a conditional promise that tuberculin shall be supplied and the veterinary surgeon paid by Government. To insist on the universal testing of herds and the immediate slaughter of all affected animals would be ruinous to farmers unless there were compensation, and compensation would involve a demand for money which no Chancellor of the Exchequer could face. It would, besides, be a premium on carelessness and neglect of hygiene. Bad farmers would get rid of sickly beasts of their own making at the public expense. The extinction of tuberculosis in cattle must, I am afraid, be a gradual process, but in proportion as it is accomplished the farmer will be a gainer because his tuberculous cows die. I have had placed in my hands an appalling list of losses of cows year after year from this disease by an intelligent and industrious farmer. In the meantime we must boil or sterilise our milk.

Prevention of the spread of consumption from persons suffering from the disease practically resolves itself into the destruction of the sputa. The sufferers themselves must be brought to understand this and to realise that unless they adopt and faithfully carry out the necessary precautions they are a standing danger to their family and friends and to the public generally. The families of consumptive individuals must be impressed with the same idea, and the general public must defend itself by insisting on what is necessary for their safety. Convenient receptacles for expectoration have been devised, and one of these patients must carry about with them and conscientiously make use of. Every night and morning, or more frequently, the contents must be destroyed, if possible by burning, and the vessel must be well washed in boiling water and cleansed by some disinfectant, a little of the disinfectant fluid being left in it to receive the expectoration. If no fire is available it is, perhaps, permissible to throw the contents of the spittoon down the water-closet or privy well mixed with a powerful disinfectant, never should they be thrown on an ash heap or out into the street or road or garden or field. Pocket-handkerchiefs should not be employed unless in the form of a square of soft paper, such as is used by the Japanese, which can be at once burnt. Some of my zealous friends advocate notification of consumption, as is done in cases of fever, but, I ask, what are you going to do with the patients when you have notified them? All the hospitals in the kingdom would not hold them, and I doubt whether any effectual inspection and enforcement of precautions would be practicable. The worry would be intolerable. And if we wait till the Legislature enforces compulsory notification years will be lost.

One form of notification, however, is already in force—the death certificate—and action ought to be taken upon this. The room or rooms in which a consumptive patient has lived and died ought immediately to be thoroughly disinfected under the supervision of the medical officer of

Digitized by Google

health. In the case of those who have received public help during life this should be imperative, and others will, I am sure, see the necessity of it in the interest of other members of the family. But there are preventive measures to be taken on the part of those as yet in health, and these are of especial importance in the case of those who belong to families in which there is an inherited susceptibility. The most effectual of these is to live, as far as possible, in fresh air day and night, summer and winter. The closely-fitting windows to which we attach such importance are a snare and a delusion. When we are sitting in a room with a fire if air cannot make its way in by the widow from the open air outside it will come in under the door from the passage and basement. Fear of a draught from a window open at the top leads to that most pernicious of draughts along the floor and about the ankles. Ventilation is of vital importance. But it is necessary by night as well as day. Everybody ought to sleep with the window open and the bedroom ought to be as fresh in the morning as when it is entered at night. I believe—it is a mere conjecture, of course—that if we all slept with open windows the mortality from consumption would be reduced by one-half from this alone. There would be fewer colds and coughs, too. The construction of houses, again, is a matter of great importance. There ought not to be a dark corner in a house, still less a dark passage. Sooner or later a dark passage or staircase will harbour germs, and, as everybody knows, they are the homes of dust. From this point of view some of the extensive flats and gigantic hotels which are now so numerous are a source of danger. In many of them the passages are tortuous and dependent on gas or electricity for light. Efficient ventilation is impossible, and as an enemy of germs even the electric light is a poor substitute for the sun. I used to be greatly astonished to meet with tuberculous disease in families living in splendid country houses, with every advantage of climate, soil, and surroundings, and all the aids to health which wealth and education can command. At last I found that the secret was dark corridors and, in one remarkable case, a dim central hall. I was chatting with an eminent man of science this summer and happened to allude to this conclusion of mine, upon which he told me that he was the sole survivor, I think, of eight brothers and sisters, and that he had lost almost as many uncles and aunts, all from phthisis, and that the family home was just such a large and imposing but dark and gloomy house as I had described. I need scarcely mention the necessity of attention to the personal health. Excesses of all kinds diminish the constitutional resistance to tuberculous invasion. Alcohol in excess not only stupefies our brains but our phagocytes, as the cells are called, which attack and destroy microbes.

So far I have said nothing of the treatment of those suffering from consumption, and you might be disposed to think that this formed no part of my subject. But it does. Nothing can be more efficacious in preventing the spread of consumption than to cure those already affected by it, unless, indeed, you kill them off out of the way. Now a great deal more can be done to arrest and cure phthisis than was formerly supposed possible by means of what is called, and what is in truth, the open-air treatment. We have been in the habit of sending phthisical patients to the shores of the Mediterranean in search of sun, to the mountain snows of Switzerland for a germ-free atmosphere, or voyages to every part of the world for the healing virtues of sea air, perhaps to special institutions in Germany or the Black Forest. Many returned better, some well, others perished miserably far from home and friends. At length we have become alive to the fact that the curative agent is not any particular air, but simply air. Thus the remedy for consumption lies ready to our hands, and instead of being attainable only by the favoured few is available for all. I hold in my hand a pamphlet by Dr. Philip, of Edinburgh, of which the title is, "On the Universal Applicability of the Open-air Treatment of Pulmonary Tuberculosis," and this is not a mere pious aspiration, but a verified experience. Dr. Philip at Edinburgh, Dr. Burton-Fanning on the Norfolk coast, Dr. Gibson in Ireland, and others elsewhere have shown that consumption can be treated successfully in practically all parts of our islands. This has revolutionised our ideas and it has created new duties. If consumption is preventable it ought to be prevented—if it is curable it ought to be cured. What is needed for this end is the erection of suitable sanatoria and these ought to be provided within easy reach of every large town. Certain requirements must be fulfilled: there must be a dry soil, a southern exposure, protection from the east and north, absolute freedom from dust, and, if possible, from fog. The special desiderata are a maximum of sunshine and a minimum of wind and wet. The construction of these sanatoria and their internal arrangements will be simple. The one thing about them will be that it shall be impossible to close the windows of any room in them day or night. They need, indeed, be little more than sleeping-sheds; but of course they would be made as cheerful and bright as possible, though pictures are almost inadmissible, as the frames harbour dust. The patient will spend the entire day in the open air, wet or fine, warm or cold. Moveable shelters will be provided to shield him from cold winds and to protect him from rain. On no pretext will he sit indoors. The amount and kind of exercise he may take will be determined by his temperature and strength, and his life will be regulated in every respect. No great barrack-like building will be required. A sanatorium will usually consist of a number of small separate pavilions, which may be erected one after the other, and I may venture to point out the opportunity to anyone who desires to be a benefactor to Huddersfield of building one of these pavilions by way of a beginning.

An idea which finds favour is that at first these sanatoria should be self-supporting—should, in fact, be for paying patients. Some part of the disease could thus be dealt with before funds could be raised to provide for consumption among the poor. The association which I have the honour to represent as chairman of the organising committee has for one of its objects the promotion of the erection of sanatoria in all parts of the country. It is to be hoped, and indeed confidently expected, that local branches will be formed for the purpose of ministering to local needs. Such branches will collect and expend their own funds and will erect sanatoria at any suitable spot in the neighbourhood so that patients will not have to go far from home. The special function of the national association will be to coördinate the work of different branches, to stimulate public interest in the prevention of consumption, and to coöperate with all the agencies which have for their object the promotion of public health.

We shall bring before county and district councils the question of milk, and aid health authorities to secure the construction of houses which shall not be standing invitations to disease, and the destruction and reconstruction of such as are, and to promote ventilation and cleanliness. Clergymen and ministers of religion, who see in the way of duty so much of the suffering and distress occasioned by consumption, will, we think, eagerly grasp the opportunity of informing themselves how the disease may be combated and prevented and of disseminating the information among families, thus reinforcing the efforts of the medical man. School-masters and mistresses, again, can do much to teach children the lessons of health and self-preservation. I have only time to hint at a very few of the ways in which a great national association may bring about the prevention of a terrible national loss and the removal of a dark blot on the national good name; and it is because more can be done by a general, simultaneous, and united effort than by any number of isolated local efforts that I give this lecture here to-day. The health authorities of the town have done me the great honour to invite me here to open formally a splendid fever sanatorium. I hope in a year or two to come down again to take part in the opening of a sanatorium for the open-air treatment of consumption, and I hope that in the not remote future, when physicians are lecturing upon tuberculous affections, it will be on examples looked upon as rare and extraordinary cases and not, as at present, furnishing a very large part of their work.

SOMERSET COUNTY ASYLUM.—The Somerset County Council has granted an additional sum of £5500 for the Cotford Asylum; the original cost was estimated at £60,000, but £154,000 have already been spent.

DIPHTHERIA IN THE RHONDDA DISTRICT.—At the recent monthly meeting of the Health Committee of the Rhondda District Council held at Pentre, South Wales, the medical officer of health (Mr. Herbert Jones) stated that a serious outbreak of diphtheria had occurred during the past month. 149 cases were reported and 31 proved fatal, the districts more particularly affected being Trealaw, Porth, and Ynishir.

An Address
ON
SOME CONSIDERATIONS OF THE LIFE AND WORK OF THE GENERAL PRACTITIONER.

Delivered on Oct. 7th at the Inaugural Meeting of the West London Medico-Chirurgical Society, Session 1898-99,

BY S. D. CLIPPINGDALE, M.D. ABERD., F.R.C.S. ENG.,
SURGEON TO THE KENSINGTON DISPENSARY.

GENTLEMEN,—It is the custom for the President of our society to select as the subject of his inaugural address the matter with which he is most conversant—in other words, his *specialty*. The specialty of a general practitioner is, or should be, general practice and it is upon this subject that I, a general practitioner, wish to offer you a few remarks this evening. I am aware that I am addressing many who from seniority and experience know more of this matter than I do myself. From them I ask forbearance if I show ignorance, while from every member I beg indulgence if my remarks lack interest.

The life and work of a general practitioner can, I think, best be studied under three heads: (1) the medical practitioner's duty to his patients and to the public; (2) his duty to other medical practitioners; and (3) his duty to himself.

THE MEDICAL PRACTITIONER'S DUTY TO HIS PATIENTS AND TO THE PUBLIC.

The duty which a medical man owes to the community generally cannot, I think, be overrated. The late Mr. Gladstone expressed his belief that medical men would eventually become the leaders of the people. Whether or not this will be so I think there can be no doubt that the influence of the medical man is increasing. The reason of this trust is, I think, due to three causes. He is known to found his opinions upon scientific facts—that is, he is a disciple of truth; he is known to possess a keen insight into human nature; and he is, I hope, always regarded as a man of honour. The evolution of the medical man, the process by which he has reached his present stage of development, is itself an interesting study.

As you are aware, the earliest practisers of the art were alchemists and astrologers. Then came the Church and to its guardianship there is no doubt that medicine owes much, for the clergy brought natural science and logic to bear upon the cure of disease. The priests were the only educated men at the time and medicine was elevated by their dealing with it. Many of the clergy made a special study of disease, and one of the Popes, I think John IV., was what would be called to-day a qualified practitioner. After a time, as medical science widened and deepened, it became necessary that a separate body of men should be trained to deal with it. Theology and medicine were divorced. Not, however, without a struggle. The new order of practitioners, like all innovators, were looked upon with suspicion. The Pope and his cardinals discussed the question whether, in the interests of the human race, the new order should be encouraged or suppressed. The cardinals, with a natural anxiety for the welfare of their people, were unanimously in favour of suppression. The Pope, so it is said, was of the opposite opinion on the ground that the new doctors, if allowed a free hand, would be sure to kill some of their patients and so prevent over-population of the world. As a strange contrast to this the Bishop of Augsburg a few weeks ago (as related in the *British Medical Journal* of Sept. 24th) found it necessary to issue an edict against what he terms "the illegal practice of medicine by clergymen" and exhorts the priests to keep faith with regular practitioners. For centuries after its emancipation from the Church medicine was little better than quackery. In fact, it is doubtful whether the term "science" can be applied to anything which existed, certainly in this country, before the time of Harvey. The estimate formed of the medical practitioner at various times may be ascertained by consulting the contemporary literature. Thus Chaucer in his "Canterbury Tales" describes a medical man and seems to think him above the average, and attributes the superiority to trusting not so much to theology as to what he calls "natural magic." The practitioners of Shakespeare's time must have had an evil reputation if we are to judge of them by the poet's writings, for in these they are generally the agents by which death is produced. In the "Anatomy of Melancholy" Burton, writing in 1621, speaks thus of the profession: "I would require Honesty in every Physician that he be not over careless or covetous, Harpy-like to make a prey of his patient, or as an hungry Chirurgeon, often produce and wire-draw his cure, so long as there is any hope of pay. Many of them to get a fee will give physic to everyone that comes when there is no cause, thus, as it often falleth out, stirring up a silent disease and making a strong body weak." A century later we find Molière writing in a venomous way about medical men—in such a way, in fact, as to lead one to suppose that he had some personal reason for the attack. Le Sage in "Gil Blas" writes in a similar strain.

The contemptuous attitude shown to the profession was perhaps more or less deserved and was probably due to the following causes. In the first place, the "doctor" was little better than a charlatan, using all sorts of filthy compounds with which to treat his patient. To him the saying may be aptly applied that he "put drugs of which he knew little into a body of which he knew less." If his remedies failed a further piece of chicanery awaited the unfortunate patient, for the "doctor" sought a consultation with a physician, not at the patient's bedside, but in a tavern or at a street corner, and the physician would there, for a fee, prescribe for a patient he had never seen. A second cause of want of esteem was possibly the fact that the surgeon often played the *rôle* of personal servant. Henry VIII., for instance, was washed by his medical adviser and the latter has left an amusing account telling us that his Royal master would only take a bath once a fortnight and then if he were in a temper would only have his feet washed. A third probable cause for the disrespect was the mercenary disposition which unfortunately but undoubtedly characterised many of the profession. This I have mentioned above and it is referred to in many books. On this matter the late Dr. James Andrew informed me that the medical men of London 300 years ago had been credited with bribing the Lord Mayor to give parties in March!

It is not until the beginning of the last century that we find the medical profession referred to with anything like respect, and then the allusions become sympathetic. The poet Pope, for instance, says of his physicians: "There is no end of my kind treatment from the Faculty; they are in general the most amiable companions and the best friends as well as the most learned men I know." Of Dr. Lettsom, the celebrated physician of the reign of George III., it is recorded that "generosity was the ruling feature of his life," and Dryden writes: "That I have recovered is owing, next to God's mercy, to the skill and care of Dr. Guibbons and Dr. Hobbs, two ornaments of the profession whom I can only pay by this acknowledgment." A study of latter-day literature will show that the medical man is growing in public estimation. Dickens and Thackeray, it is true, write in satire of the profession; but satire is characteristic of these distinguished novelists. In the modern novel the medical practitioner often receives an amount of adulation which is fulsome, but honest tribute is to be found in the writings of the American poet Whittier, the late Mr. John Timbs, Mr. Cordy Jeafferson, Mr. Symington, Mr. William Andrews, and many others, while sympathetic articles are constantly appearing in the journals, notably the kindly and graceful writings in the *Spectator* last year. With his position in public favour firmly established and with the look for guidance from his fellow-men, how is the practitioner to discharge his trust? and firstly:

What part should a medical man take in municipal or imperial government? I have never felt free to respond to invitations to go upon a local board. It has always seemed to me that the contentions which often characterise the proceedings of these boards are incompatible with the calm required for medical practice and I am of opinion that the work of these boards is best left to the excellent business men who generally compose them and to their responsible medical advisers. With regard to the House of Commons it should always be remembered that a medical man who becomes a Member of Parliament does so as the representative of one or other of the political bodies. When he speaks he is listened to, not as a medical man, but as the agent of the party he represents. The political doctor is in my mind as unsatisfactory as the political parson, and for a

Digitized by Google

medical man to achieve success as a politician appears to me to amount to a confession that he blundered in choosing his career. Government wants guidance in matters of health, but should not they get this as they get guidance in matters of law? Corresponding to the law officers of the Crown should there not be a Minister of Health—a medical man of great repute. The Minister of Health would of necessity be changed with the change of Government, but this would ensure that the post would always be filled by an up-to-date man. With a medical man as Minister of Health we should cease to witness the curious phenomenon of medical questions being answered by a gentleman who may perhaps be a successful brewer. As to the representation of the profession itself in Parliament I fail to see why it should not be represented where the other two professions are represented. I cannot believe that the House of Lords would suffer in dignity or in utility by the creation of a certain number of life peers on the nomination of bodies like the Royal Colleges of Physicians and Surgeons. With regard to the public services, it is a satisfaction to note that the office of coroner is now frequently given to a medical man who has taken the trouble to graduate in law also, the first appointment of this sort in London being that of Dr. Luxmoore Drew, the admirable coroner of this district. As to the military services, voluntary or regular, we must rejoice that our comrades in arms have at last received the positions and titles which they justly deserve; but I think we should deprecate a disposition on the part of our military brothers to forget that they enter the army as medical officers or a desire to exchange the medical for the military spirit. Doing this has been compared by Brigade-Surgeon Climo, and I think rightly compared, to the child who, possessed of a priceless jewel, prefers the setting.

What duty does a medical practitioner, as a teacher of hygiene, owe to those with whom he may come in contact? This duty is one of increased importance now that the Legislature has declared that a man may place his "conscience" above the law, especially as this so-called "conscience" seems to be the peculiar possession of ignorant people. It is also the duty, I conceive, of every medical man to point out that the object of medicine is its own obliteration, that death should follow senile decay alone, and that the stamping out of disease is a possibility, though its realisation will be delayed by the misguided action of faddists and "antis."

In what way can the medical practitioner best discharge his duty to his patients? It has been said that a good practitioner will aim at becoming as efficient as possible and then see that his patients get the benefit of his knowledge. I think it would be well if we asked ourselves occasionally such questions as these: How often do I attend the meetings of the Medical Society? what part of my annual expenditure in books goes in the purchase of medical literature? do I utilise my holidays in any way for the benefit of those who enable me to enjoy them? With regard to the last of these questions I may say that it has been my custom for some years to spend my holidays in health resorts. In this way I have had many pleasant trips, not only to the most picturesque parts of these islands, but also to such places as Arcachon and Biarritz, the health resorts of the Pyrenees, the Riviera, in Switzerland and in Germany, and I have seldom failed to find the knowledge thus acquired of benefit to my patients. The late Dr. Wilson Fox addressing his students said, "When taking your holiday, if you are anywhere near a health resort, by all means go and see it." I would venture to say, "Go to the health resort while engaged in active practice for your holiday and if you are anywhere near a golf course, &c., go to it." The late Archbishop Trench on this subject wrote:—

> "They who bid stern duty lead,
> Content to follow, they,
> Of duty only taking heed,
> Find pleasure by the way."

The practitioner who, having seen a patient at a distance, with the knowledge that he has done good and been well paid, with half an hour before his return train starts, and being of an antiquarian disposition turns into the aisles of an ancient cathedral, derives infinitely more gratification than if he had made the journey in pursuit of pleasure. The late Sir Andrew Clark, at a dinner of this society, made, as many of us will remember, some trenchant remarks about the man who prefers the theatre to the medical society, the novel to the medical journal, and, having stated that he came as a matter of duty but with a splitting headache, said that a man succeeded just as he was able to put his sensations under his foot and crush them! Gentlemen, if I speak something like a pedagogue I pray you forgive me. I am sensitive on this matter, for I feel no one needs greater stimulation to work than myself.

How can a medical man, having taken pains to make himself as proficient as possible, benefit his patients by the knowledge thus acquired? Turning to this question, I would suggest that a man often fails through want of confidence in himself. The late Prince Bismarck, when asked why he selected as his medical adviser the youthful Dr. Schweninger when there were so many older and better-known men in Berlin, replied: "The difference between Schweninger and my former doctors lies in this—I treated them, Schweninger treats me." Sir Morell Mackenzie and Dr. Burney Yeo have both pointed out that the medical practitioner should always be *superior* to his patient. The patient, in fact, feels *weak* and seeks *support*. He is the *adjective* and needs the medical man as a *noun* to lean upon.

THE DUTY OF THE MEDICAL PRACTITIONER TO HIS BROTHER PRACTITIONERS.

I wish to point out that the public have a curious notion as to what is called "professional etiquette." "You doctors are so funny," a patient will say, and he insinuates that "professional etiquette" is a variety of trades-unionism existing for the benefit of the medical profession and to the detriment of patients. It is not easy to make him believe that "professional etiquette" is simply the practice of the Christian rule of doing to others as you would have others do to you. The peculiarity of the medical practitioner, however, is that he carries this rule out more faithfully than others. The clergyman, for instance, does not expel from his congregation the person who lives in another parish, the lawyer does not refuse advice to a client who has consulted another lawyer, and the tradesman assuredly takes delight in getting his neighbour's customers. To a young practitioner, however, who wants to pull well with his colleagues I would strongly advise a perusal of Mr. de Styrap's excellent work on "Medical Ethics," and the report upon the same subject by the Shropshire branch of the British Medical Association. A study of these works and a careful consideration for the feelings of others would, I think, lessen the number of painful revelations which we are accustomed to see in the correspondence columns of the medical journals.

What duty do we owe to our brother practitioners in the poorer parts of London? We who live among cultured people, near parks and museums, who receive remunerative fees, and are shown hospitality by our patients, are, I fear, but ill-acquainted with the struggles of our equally deserving brethren who practise exclusively among the poor. I am not certain whether we do not look upon them with something like contempt and complain of the small fees which they unfortunately are obliged to accept. Yet surely the poor man's shilling is as respectable as the rich man's guinea and the poor man's medical attendant is generally one of vast experience and often a man of culture. I am acquainted with the case of an old Eton boy who has to receive a smaller fee than a shilling. To help these, our less fortunate brethren, is indeed a difficult problem, but I think a hint may be taken by what is known as the "affiliation among the Churches"—that is, a scheme by which a rich parish helps a poor one. The idea as regards medical work is certainly at present impracticable and may be altogether impossible, yet I can conceive that upon recognised and equitable principles an interchange of practices would be possible and beneficial. The West-end practitioner would be glad to realise the hardships of his less fortunate brother in the East. The East-end man would find relief by a stay in the West. An outcry would be raised by our wealthy patients, but they would have to follow us into the East and bring their wealth with them.

What is our duty in the matter of consultation? I think it should be clearly laid down that one general practitioner should never meet another general practitioner in consultation. Not for fear of arousing jealousy but simply in the patient's interests. If two men practising on the same lines and receiving the same fees meet in consultation they must either agree or disagree. If they disagree the patient is placed in the awkward or impossible position of deciding between them. If they agree the patient gains nothing. The entire body of consultants is within easy reach of us and if the patient cannot afford the fee for the consultant's advice he should seek that advice gratuitously at the hospital. As to the consultants we call in I fear there is a tendency to select our old teachers or our personal friends, and our old teachers and personal friends are rather apt to recommend us as private practitioners to the exclusion of perhaps better

Digitized by Google

men. I think the interest of the patient alone should guide in such matters. The consultant whom we summon to our patient may not be the consultant whom we should select for ourselves or families, but there may be many reasons in the interests of our patients to influence us, and the interests of our patients should, I think, be our sole guide. A class of practitioners which I cannot understand includes the men who while engaged in general practice pose as specialists and the consultants who engage in general practice. In this neighbourhood I fear it is not uncommon for a consultant to visit a patient alone. He does so in the first instance for a smaller fee than he would receive in consultation and sometimes pays a second visit without fee—a "friendly" visit he calls it. In this way he enters very closely into competition with the general practitioner. Would it not be better for the practitioner of either kind to restrict himself solely to his proper work? The medical sphere is such a large one that it requires a man's entire energy to discharge properly his duty in the branch which he has selected for his own work.

> "One science only can one genius fit—
> So deep is human knowledge, so shallow human wit."

THE GENERAL PRACTITIONER'S DUTY TO HIMSELF.

If a general practitioner takes pains to make himself efficient, and if he lets the patient benefit by his efficiency, he is certainly entitled to look to the patient for adequate remuneration, and yet how often is he doomed to disappointment? The lines quoted in his presidential address by Dr. Alderson are too often true:—

> "God and the doctor we alike adore
> When sickness comes, but not before;
> The danger over, both are alike requited,
> God is forgotten and the doctor slighted."

To secure prompt remuneration I think it would be better if we could follow the example of barristers, of consultants, and of medical men in Ireland and in some places abroad—that is, to secure our fee at the time of our attendance. "The sick man," someone has said, "pays willingly while his tears are wet." Our custom of keeping books and rendering accounts, while it savours of the custom of tradesmen, is often, I think, the cause of serious loss to our pockets.

In the care of his health I fear the general practitioner is too heavily handicapped by the nature of his work to take much heed. For instance, no conscientious practitioner can take an hour for a meal and rest in the middle of the day if the patient who sent early in the morning has not yet been seen. The lunch is postponed. The digestive organs, ready with their juices to receive and digest the expected meal, think their agency is not required and resume a state of inactivity from which they are rudely awakened one, two, or three hours afterwards. They are then called upon for extra work, get worn out early, and dyspepsia results. I think it better to take at the usual meal hour a mere *soupçon* of food, if there is not time for a proper meal, and then wait for the next regular meal hour for a fuller supply. The disturbed sleep, the exposure to weather, the anxiety caused by difficult cases are all matters over which I fear a medical man has little control. No wonder the average years of his life are as low as fifty-seven. He must accept the pains as well as the pleasures of his profession and can only look forward to retirement to be freed from the former and to dwell with gratification upon the latter.

In the matter of recreation I think that no medical man should be without his hobby. It has been said that a man who sticks sufficiently closely to his work finds in it his recreation as well as his means of living. The nature of the practitioner's work, however, demands that his mind shall be abstracted at times from things morbid. The neglect of this demand is liable to be productive of misery when the time comes for cessation of active work. A celebrated physician complained to his friend in these terms: "I am told I must retire and make way for younger men. I have done nothing all my life but physic people and now I am told to go into the country and grow cabbages." I grieve to know that this distinguished man's period of retirement is not as happy as it should be. Lord Bolingbroke, the celebrated statesman of Queen Anne's reign, said, "Blessed is the man who has a hobby"; and a well-known medical man has said, "If you cannot find pleasure in the study of geology, of natural history, or of astronomy, then by all means make a collection of old walking-sticks, postage stamps, or pieces of cracked china."

Finally, I would advise a *spirit of contentment* as conducive to happiness in a general practitioner's lot. His work is surely a creditable one. The necessity of being able to deal efficiently with disease in all its forms at all times, the ability to treat successfully persons of all ranks and of all tempers, surely compel the possession and the exercise of knowledge and tact which are not surpassed in energy and self-denial by the requirements of any other branch of practice. It is a pity for the medical practitioner having put his hand to the plough to look back or to look above. I am sure many of our consulting brethren could tell us bitter tales of the struggle of their earlier years. In general practice there is much, if we only look for it, to interest and instruct us; much to keep our sympathies green and our spirits contented. Mr. Fildes's picture, the picture which attracted so much attention a year or two ago, did not pourtray the court physician, whose name is in the paper every day, nor the popular specialist who is the idol of society. The picture represented the general practitioner in the humble cottage, watching the sleeping child and thinking what he will have to tell the parent, and watched himself by the anxious parent trying to forecast what he will have to hear from the doctor. The picture recalls the lines written upon a portrait of the late Mr. Merriman of Kensington:—

> "What does it tell us? That to thee
> The noblest task on earth was given,
> The brightest service that we see
> Conferred on mortal under Heaven.
> To heal the sick, to lighten pain,
> To gently cool the heated brow,
> And, like an angel, bring again
> Hope to the hopeless, such wert thou."

I have referred to the ingratitude of patients, but how often do we receive from them touching evidence of their esteem and affection? How many of us can display valued, if not always valuable, gifts? It is said that a medical man should have his coat made with two pockets—one for his fees, the other for his insults. But is not a third pocket sometimes necessary—one to receive these welcome gifts?

There must surely be something in medical practice to awaken the emotions and stimulate the intellect, for we find the highest forms of literature enriched by the contributions of members of the medical profession—witness the works of Goethe, Sir Thomas Browne, Goldsmith, Smollett, Sir Samuel Garth, Sir Richard Blackmore, Akenside in the past, and besides others Oliver Wendell Holmes, Conan Doyle, and John Watson in the present day. How many of us could write, founded upon our cases, histories like the "Diary of a late Physician" by Samuel Warren, who was a medical man as well as a lawyer? At Monte Carlo one of the English surgeons there informed me that his patients suffered not so much from physical ailments as from nervous tension and exhaustion the result of gambling, and that they went home not with health improved by the climate of the Mediterranean, but with constitutions shattered by excitement.

The family doctor is, perhaps, more than either the clergyman or the lawyer the family friend. He is seen more frequently than either of the others and is consulted about many matters which are not medical. He is looked up to with childlike faith for advice which it is known will be given with neither satire nor contempt. It is his duty to minister to the wounded spirit as well as to the weakened body. In my own case I have been encouraged to do this by the motto of my alma mater, the London Hospital—*Nihil humani alienum puto.*

A CASE OF CHRONIC INFANTILE MENINGITIS WITH BASAL DRAINAGE.

BY WALKER OVEREND, M.A., M.D. OXON.,
PHYSICIAN TO THE TOTTENHAM HOSPITAL;
AND
W. FOSTER CROSS, M.R.C.S. ENG., L.R.C.P. LOND.,
RESIDENT MEDICAL OFFICER TO THE HOSPITAL.

THE following case is of interest because of the extreme degree of rigidity which gradually became established and also because of an attempt which was made to drain the lateral ventricles through the subcerebellar space. Parkin[1] was the first to perform this operation and gave it the name of "basal" drainage to distinguish it from "cortical" (that is, drainage through the fontanelles and direct puncture

of the lateral ventricles) and "vertebral" drainage. Subsequently Waterhouse[2] drained the same space in a case of tuberculous meningitis. Glynn and Thomas[3] in 1895 described a case of chronic hydrocephalus in a young man subject to severe headaches, insomnia, and sickness in which the skull was trephined in the occipital area and drainage established, the result being perfectly satisfactory.

The patient, a female child aged ten months, was admitted into Tottenham Hospital on Feb. 16th, 1898. About three weeks previously she fell on her head out of a chair and was sick on the next day with convulsions. She afterwards gradually fell into a drowsy insensible state. Two days before admission she had several screaming attacks and at the same time retraction of the head was noted, but no strabismus. On admission she appeared to be semi-comatose and took no notice. The head was not retracted. The pupils were equal and reacted well to light. There was neither strabismus nor nystagmus. The heart and lungs were normal. There was no tenderness or retraction of the abdomen. The temperature was 97°F. The fontanelles were widely open. During the day the child vomited once. On the 17th the temperature rose to 101°. On the 23rd a vesicular eruption appeared on the face, trunk, and limbs, varicelloid in character. This afterwards became purulent and left scars. On March 5th the vomiting had continued and had gradually become worse. Nasal feeding was now commenced and continued throughout the illness. On the 8th a mixture of peptonised milk and chicken broth was given as food and 1 gr. of hydrargyrum cum cretâ every night. As a result the vomiting ceased. On the 11th a purulent discharge commenced from both ears and the temperature again rose to 101°. On the 14th a convulsive attack occurred lasting thirty minutes and the temperature rose to 102°. As the convulsion was not relieved by a hot bath a few whiffs of chloroform were inhaled. The convulsion was general, with arching of the back and retraction of the head. An enema of bromide of potassium (5 grains) and chloral hydrate (1½ grains) was ordered. A lotion of perchloride of mercury (1 in 3000) had been used for syringing the ears. Sherry whey was added to the chicken broth on the 11th and mercurial ointment had been daily rubbed into the abdomen and spine. On the 14th the vomiting also returned and the food was altered to peptonised milk and chicken broth. On the 19th the temperature reached 104° and the breathing was of the Cheyne-Stokes type. The optic discs were somewhat blurred, the veins were full and tortuous, but there was no marked retinitis. On the 26th there had been no more convulsions. The temperature chart was irregular and oscillating. There were now well-marked opisthotonos, retraction of the head, and carpo-pedal contraction. On April 27th the condition was unaltered as regards the rigidity, but the head now began to increase in size. Its circumference measured 19 in., the forehead was prominent, and the sutures were widely separated. Rigidity was extreme. The fingers were clenched, with the thumbs turned inwards, the forearms were prone, and the arms were extended. The legs were extended to such a degree that the feet touched the pillow and were on the same level as the retracted head. The tibiæ were rotated outwards and the knee-joints were rigid. The feet were extended and rotated inwards. The great toes were drawn inwards towards the sole. Nystagmus was present to a slight degree and strabismus occurred at times. On May 1st, the head having been prepared for operation in the usual way, Mr. Carson made an incision under chloroform from the external occipital protuberance towards the right mastoid process and turned down a flap of skin. The periosteum was stripped off and a portion of bone between the curved lines about half an inch in diameter was removed. The dura mater was exposed and opened. A bent probe was introduced as far as the tentorium and turned into the fourth ventricle, when about 2½ oz. of clear fluid escaped. A drain made of silk strands was introduced and left inside; the wound in the dura mater was stitched up, skin sutures were inserted, and the wound was dusted and dressed antiseptically. Very little hæmorrhage occurred and the operation proved easy of execution. The child bore the operation well. On the 5th the temperature had now been normal for two days. The child appeared to be somewhat better; there were less retraction of the head and rigidity of the limbs. The arms and legs were massaged daily and the child retained food well. On the 12th the child steadily became weaker. The stitches were removed on the 7th. The wound had healed and there was still a slight discharge of cerebro-spinal fluid. Death occurred on the 23rd. The illustrations show the posture assumed by the child on the day before death.

At the post-mortem examination great thinning and flattening of the cortex were noticed, with hyperæmia of the pia mater. Over the fourth ventricle and sella turcica the membranes were opaque and thickened. The ventricles were enormously distended with clear fluid and on removing the brain a large quantity of clear fluid escaped from the sides at the base, evidently from the posterior subarachnoid space. The iter and third ventricle were enormously enlarged. The lateral ventricles were so greatly distended that the brain appeared as a mere shell enclosing a reservoir of fluid. The ependyma and septum lucidum were much thickened. The choroid plexuses were relatively insignificant in size. There was no fracture of the bone, no laceration of the brain, and no suppuration within the temporal bones. The purulent discharge from the ears lasted only a few days and was obviously due to dental irritation and not to middle-ear trouble. The spinal cord was healthy and the central canal was of normal dimensions. There was no evidence of syphilis and there were no tubercles.

The causal relation of traumatism to the symptoms appears definite and direct, although the fact that the fontanelles were widely open on admission might lead one to suppose that a chronic hydrocephalus independent of the accident had already commenced. On the other hand, the coma and sickness began immediately after the fall and gradually became more severe during the four months the child survived. It is true that neither fracture nor laceration was discovered at the necropsy, but a laceration might have had time to heal and become obscure. There was certainly much thickening over the sella turcica and in the subcerebellar region. Obviously the result of the injury was to irritate the secreting cells of the ependyma, block efferent lymph channels, increase the circumference of the head and particularly the vertical measurements from ear to ear across the anterior fontanelle.

The operation in itself is not difficult nor is it attended by any special risk. Although the child was in a wretched and impoverished condition she bore the operation well and even improved somewhat afterwards. To be of any use, however, it should be performed as soon as the measurements of the head begin to increase, otherwise the lateral ventricles become dilated beyond any hope of amelioration. Drainage by means of silk strands we found to be unsatisfactory and in future we should be disposed to use capillary rubber tubes provided with an arrangement for preventing the too rapid escape of fluid.

ON COMBINED PLEURAL AND PERICARDIAL ADHESION.[1]

BY FREDERICK TAYLOR, M.D., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

MANY years ago I remember to have seen a case which appeared to give much difficulty to my seniors who were in charge of it. I was then scarcely in a position to form an opinion for myself, but I remember that a diagnosis of double pleuritic effusion was made. In the absence in those days of exploring needles this diagnosis was during life neither proved nor disapproved, but after death it was found that both pleuræ were universally adherent, very much thickened even to the thickness of ½ in., and that the pericardium presented a precisely similar condition except that the actual thickness of the fibrous layer was less in the case of the pericardium than the pleura. The case made a great impression upon me, but I have never been led to make much of the bearings of it until one somewhat similar presented itself in the latter half of last year under my own care in Guy's Hospital.

A woman, aged forty-two years, was admitted on May 20th, 1897, for dyspnœa, cough, and pain in the chest. The patient's father and an uncle had died from phthisis; her

[1] A paper read before the Nottingham Medico-Chirurgical Society on April 27th, 1898.

Digitized by Google

mother died from bronchitis at the age of seventy-five years. Four years previously the patient had had scarlet fever. In February of this year an adeno-myxoma was removed from the left breast by Mr. Arbuthnot Lane. About Christmas she had noticed that her abdomen was growing larger, but without pain. Towards the end of April she had a slight cold and she said that on the 27th she had slept in a damp bed. The next day she had chill and shivering, dyspnœa, pain between the shoulders, and cough. On the 29th she was rather better, but worse on the 30th, and so she continued until May 2nd, when she laid up and was attended by Dr. James Wills. The feet and legs were then observed to be swollen. After that her condition varied, the dyspnœa being sometimes so great that she could not walk about; the pain also varied as to position. On May 15th Dr. Newton Pitt saw her in consultation and the chest was explored with a needle at the right base, but no fluid was found. On admission she was seen to be a middle-aged woman, with dark hair turning grey, dark eyes, and sharp features. The face was flushed and slightly swollen; the legs and feet were slightly swollen and there was œdema over the sacrum. Otherwise she was thin. The breathing was quiet and shallow and she had a hard dry cough. The chest was flat and the epigastric angle was less than 90°; there was no sucking in of intercostal spaces. The two sides moved equally. Tactile vocal fremitus was normal in front but deficient at the right base behind. Both bases were dull behind, the right up to one inch below the angle of the scapula, the left up to one and a half inches from the angle; there was resonance elsewhere. The vesicular murmur was absent from both bases over the dull areas; elsewhere it was normal. Fine inspiratory râles were heard at the left base behind and at both bases in front. The pulse was 96, regular, feeble, soft, and compressible. The impulse of the heart could not be seen, it was just felt in the fifth space, an inch below the nipple and half an inch internal to it. Præcordial dulness was limited above by the lower border of the fourth rib, and internally by the left border of the sternum. There was no murmur. The abdomen was tense and slightly swollen and there was some œdema of the skin on the left side. There was some dulness at the sides, but it did not move with change of position. The temperature was 99·4° F., the pulse was 96 and the respirations were 38. A week later the condition was much the same. There were dry cough, dyspnœa amounting to orthopnœa, and pain in the left side of the chest. At the right base there was still absence of breath-sounds and tactile vibration and at the left base the breath-sounds and tactile vibration were very deficient. A few days later there was some increase of râles in front on the right side, but the bases were thought to be less dull. The urine on May 31st was free from albumin, but it contained a slight amount on June 3rd, which amounted to 0·5 per 1000 (Esbach). At this time also the urea was found to be on two separate occasions 10 grs. and 12 grs. per ounce. During the month of June she became more œdematous, the abdomen increased so as to measure 31½ in. in circumference, there was much œdema over the sacrum, and the feet and legs and face swelled more. During July and August also there was no material difference, only an increase of the dropsy in every way and a persistence of the physical signs of the lungs. The abdomen increased to 39½ in. in circumference, due partly to ascites and partly to cutaneous œdema, which extended round the loins to the back and reached up to the angles of the scapulæ. At both bases the chest was dull, the entry of air was deficient, and râles were audible. The right side was slightly worse than the left. In front some râles were audible below the third rib. By the beginning of September the œdema extended to the upper extremities and the face, but was very variable in these parts; on the 21st the pulse was 104, the respirations were 50, and the temperature was 97°. The condition of the chest was as before. There were no cardiac bruits. The lips were full-coloured and congested. Examination of the fundus of the eyes gave negative results, there being no neuritis, retinitis, or hæmorrhages. During October some relief was obtained by puncture of the swollen legs. On Oct. 14th the patient had a rigor lasting ten minutes, on the 15th one lasting twenty minutes, and on the 24th a third, more severe, lasting nearly an hour. On Oct. 26th dulness was noted on the left side of the chest in front and some râles under the left clavicle; the posterior dulness extended quite up to the scapular angles. From this time she became more drowsy and collapsed, and she died on Nov. 7th. The temperature had been nearly always normal or subnormal. Only on two or three occasions for a few days at a time during the last three weeks of her life did it rise to 101° or 102°.

At the post-mortem examination the face and arms were found to be very thin and the abdomen and legs were œdematous. Both pleuræ were thickened all over and both surfaces were tightly adherent. The pericardium also was firmly adherent all over, so that it could be peeled off the heart, and it also was much thickened. Further, there were dense pleuro-pericardial adhesions and much fibrous tissue matting together the vessels and other structures in the mediastinum, the results, therefore, of a mediastinitis. The lungs were small and compressed, and quite airless except at the apices. The bronchial tubes were very much dilated at the left base, but less so in other parts. The bronchial glands were normal. The right auricle was dilated and the right ventricle was dilated and much hypertrophied. The left ventricle was very small and its walls were not thickened. There was no endocarditis; the valves were healthy, and the orifices measured as follows: the tricuspid, 4¾ in.; the pulmonary, 3½ in.; the mitral, 3½ in.; and the aortic, 3¼ in. The peritoneum was universally thick and opaque, especially on the pelvis and on the under surface of the liver. Over all this, especially in the pelvis, was much recent lymph. The liver was compressed from before backwards, and the capsule was thickened, involving the gall-bladder, which contained a gall-stone of the size of a filbert. The gastro-hepatic omentum was contracted. The spleen was hard and small, with a thick capsule, and it was adherent to the left lobe of the liver. The kidneys were small and healthy.

As will be seen the features of this case are, *clinically*, abolition of the action of the bases of both lungs without certain evidence of liquid in the pleura, cardiac weakness without marked local evidence of the heart's failure, with early and somewhat pronounced ascites. *Pathologically* they were adherent pleura with extensive collapse of the bases of the lungs and some dilatation of the bronchial tubes adherent pericardium with dilatation of the right auricle and ventricle, chronic mediastinitis (non-suppurative), and ascites with evidences of chronic peritonitis.

The mere coexistence of fibrous adhesions of the pleura and pericardium is sufficiently common. I find that in Guy's Hospital the post-mortem records of nine nearly consecutive years show that there were 192 cases of adherent pericardium, and of these 58, or nearly one-third, were accompanied by thickened or adherent pleura. On the other hand, the analyses of the clinical reports of cases in the medical wards show that only once in three or four years was thickened pleura recognised or diagnosed in association with adherent pericardium. This is, of course, only an illustration of the well-known fact that each of these lesions may present considerable difficulties in diagnosis. I have, however, examined more closely the post-mortem records for one year (1892), in which adherent pericardium was noted 25 times, and in 10 of these cases the pleuræ were also thickened or adherent. Of these 10 cases 3 presented valvular lesions which became the chief feature during life, in 3 the adhesions of the pericardium concerned only very small portions of the heart's surface, in 1 there was a hypertrophied heart with granular kidneys and the pericardial adhesions were limited, and in 2 the patients had undergone operations in surgical wards and died from syncope (fatty heart) and broncho-pneumonia respectively. The last 3 cases showed evidence of former phthisis. One only of the 10 cases presented some resemblance clinically as well as pathologically to the case I have just recorded. The right pleura was universally adherent and the left chest contained 22 oz. of serum and showed recent lymph over the lower lobe. The pericardium was universally adherent with calcareous plates in it. The heart weighed 14 oz., and was hypertrophied, and all the cavities were dilated. The muscular tissue was fatty. The patient had had during life dyspnœa, palpitation, and attacks of faintness; there were œdema of the feet, albuminuria, rapid pulse (140), and albumin in the urine; there was no cardiac murmur.

It is with this last class of case that I propose to deal for the present, especially from the point of view, at least in my own cases, that the pleural lesions were very extensive and of great prominence clinically, and that conversely the adhesion of the pericardium was suggested only by the failure of the circulation, not at all by any local manifestations and very little by any changes in the pulse. I have no doubt there are other cases like it and perhaps they are

Digitized by Google

more frequent than I have been led to believe, and possibly the problems may seem to others easier of solution than they do to me; but I believe that in any case, whether rare or frequent, they form a group somewhat apart from other cases and are worthy of consideration.

One of the first questions is as to their origin. There are, no doubt, many circumstances under which pericarditis and pleurisy may be co-existent or consequent one upon the other; the most familiar is the case of double pleurisy in rheumatic fever accompanying pericarditis. The effusion in the pleura is often extensive, at least on one side, but it is not common to see at one and the same time a complete double pleurisy and pericarditis in rheumatism, and any approach to such a severe extension of the lesion would very probably be fatal. We are familiar also with the complication of pericarditis in acute pleuro-pneumonia, with double pleurisy and pericarditis in pyæmia, and with tuberculous pleurisy and pericarditis simultaneously. But all such explanations of this case present difficulties, seeing that on the one hand we cannot suppose these conditions are the sequelæ of tubercle or pyæmia, and on the other the patient gives no history either of rheumatic pleurisy or of so-called catarrhal pleurisy at such a date preceding her final illness as would explain the lesions found. It may be suggested that in her twelve months' illness the early catarrhal or acute or subacute inflammatory stage occupied the first months and the fatal mechanical results occupied the later periods; but it will have been noticed that the first symptom twelve months before her death was a swelling of the abdomen, which, as I shall show, is consistent with the probability that adherent pericardium with accompanying cardiac failure was already in evidence. It is, of course, allowable to speculate on the scarlet fever of four years previously to her admission to hospital as having been followed by rheumatism or as in some other way having been the antecedent of the implication of the serous membranes. But in that case it is remarkable that she should have at some former period of her life undergone such extensive lesions without having any recollection of the illness and discomfort to which, one would think, they must have given rise. Still, so far as mere antecedent is required, it will be only consonant with modern pathology to regard the scarlet fever and other infectious diseases—e.g., influenza—as sufficient.

Now, turning to the relation between the post-mortem lesions and the clinical symptoms the question presents itself: Are the latter determined by the conditions of the lung—adherent pleura and dilated bronchial tube; or by the conditions of the heart—adherent pericardium and dilated right side; or by the condition of the mediastinum, so-called "mediastinitis"? or what share has each in this production? In the answers to this question we should find, if we can at all, some help towards diagnosing this combination in the future. Beginning with the lung and pleura we find that the physical signs were dulness at both bases, especially the right, and deficient entry of air with some fine râles. The symptoms related to the lung were directly orthopnœa and cough, and indirectly dropsy of the legs and the lower part of the body. It is an old story that thickened pleura will account for dulness at the base of the lung, and when the thick adherent pleura is accompanied by collapse of the underlying lung the occurrence of the physical signs is easily explained. The latter was present here and to it, indeed, the dulness and deficient entry of air must be ascribed. Indeed, I should like to take the opportunity of expressing the view which I have long taught, that the dulness which so commonly persists for a long time after a pleuritic effusion is not due, or due in but small part, to the thickening of the pleura, but rather to the still unexpanded lung, which has been compressed by the fluid previously there. Neither could the thickening of the pleura have much share in the production of the œdema; but the sum total of the pulmonary lesions, especially the collapse of the substance and the dilatation of the tubes, no doubt contributed to that dilatation and hypertrophy of the right heart which was the chief cause of the œdema. In so far as the duration of the adherent pleura is concerned I need say little about that. We know from abundant experience that the pleura is constantly found adherent on one side in cases where, no such condition has been for a moment suspected and where, indeed, so far as the chest is concerned, the patient may have been thought to be perfectly sound and normal. It is possible that the adherent pleura had a share in the production of the dilated tubes, but as there were no signs during life by which they could with certainty be recognised but little help is derived from that view.

It must of course be seen that the chief explanation of the dropsical symptoms lies in the two conditions which the heart presented—namely, adhesion of the pericardium and dilatation of the right heart. Here, again, we are in some difficulty as to the importance of mere obliteration of a serous cavity, and it is clear that the adhesion can only act prejudicially if it causes the occurrence of hypertrophy or dilatation of the cavities of the heart. Even whether it can do that is somewhat doubtful, and the explanations of the coexistence of adherent pericardium and dilated heart are more than one. A simple explanation is that accompanying the pericarditis there is some inflammation of the myocardium—myocarditis—which results in the altered physical conditions. Dr. John Broadbent, in his work on Adherent Pericardium, has provided us with the suggestion—viz., that when the heart dilates as a result of the yielding of the inflamed muscle it is subsequently maintained in this dilated condition by the fibrous changes which take place in the simultaneously inflamed pericardium; and he points out that the right ventricle is more likely to suffer than the left. This was, indeed, the case here; but it would be rash to deny the influence of the pulmonary conditions on the production of this right-sided failure. It may be remembered, so far as diagnosis is concerned, that the impulse of the heart was in the fifth space internal to the nipple, and the percussion dulness did not pass beyond the left border of the sternum. So far, then, it seems probable (or certain) that the dropsical symptoms must be referred to cardiac failure and that a failure on the right side rather than on the left.

When looking for references to literature bearing on the present case I met with some articles by Dr. Heidemann which have a very important bearing upon it and which possibly provide a solution of the difficulties which it presents. His paper is entitled "On the Results of Obliteration of the Pericardium."[2] After reminding his readers that adherent pericardium eventually leads to all the effects of cardiac failure, however arising, such as dyspnœa, œdema, and dropsical effusions, with small, rapid, and often irregular pulse, and that these conditions are now allowed to be the results of a myocarditis coincident with the pericarditis which caused the adhesions, he states that not all cases run the same course and draws especial attention to cases in which ascites was the first prominent symptom and that often long before any anasarca or œdema of the feet was observed. He refers to isolated observations of a similar kind by Hirschler, Riegel, and Pick, and to statements by Rosenbach, Strümpell, Leube, and Schrötter, bearing in the same direction. He then records his own case and follows with 6 other cases already published by Van Deen, Frerichs, Vierordt (2 cases), Riedel, and Henoch. In all of these 7 cases the peritoneum, besides containing fluid, was thickened, or it showed evidences of chronic inflammation. In all of them, with the exception of one in which the thoracic conditions are not given, there was pleurisy either in the form of fluid, or of a thickened pleura, or of extensive and complete adhesions; this was present in two cases. Three of these cases were published as cases of chronic exudative peritonitis, and probably the pericardial obliteration was not a prominent feature clinically or was perhaps overlooked; another is in Frerichs's work on Diseases of the Liver under the heading of Simple Induration of the Liver, which Frerichs attributes to the operation of peritonitis in this case.[3] A fifth is published as chronic pericarditis in combination with chronic pleurisy and peritonitis, and the sixth is from the "Diseases of Children" of Henoch, who regarded it as a case of syphilitic pericarditis and myocarditis. After reviewing and discrediting the opinions of some authors who attribute the early appearance of the ascites to cirrhotic conditions of the liver, or to peculiarities in the circulation of the liver, or to kinking of the vena cava by fluid in the right pleura Dr. Heidemann adopts the suggestion of Weiss that antecedent to the cardiac failure there is, or has been, an inflammatory condition of the peritoneum which favours the occurrence of dropsy in this part of the body rather than in the so far uninjured connective tissues of the lower extremities. Similarly, where the pleural surfaces are not adherent hydrothorax

[2] Ueber Folgezustände von Pericardialen Obliteration, Dr. M. Heidemann, Berliner Klinische Wochenschrift, 1897, Nos. 5 and 6.

[3] Frerichs: Diseases of the Liver, Sydenham Society's Translations, vol. ii., p. 98.

Digitized by Google

will readily result from cardiac failure as it comes into operation. Thus, what is suggested as the course of events in these cases is the more or less simultaneous occurrence of peritonitis, pleurisy, pericarditis, and myocarditis; cardiac incompetence as a result of the last; and serous effusions antecedent to anasarca of the limbs in consequence of the tissue-weakening of the serous membranes.

If we ask the cause, the primary cause, of all this the answer is by no means satisfactory. The micro-organism is always, of course, at hand. Dr. Heidemann says: "It is astonishing that the disease so often attacks the upper part of the abdomen and especially in this part leads to cicatricial processes and extensive matting together. One may well believe that micro-organisms are the excitants of the disease and that after their entry into the abdomen they are carried about by the peristaltic movements of the intestines, "remain fixed in the closed spaces between the diaphragm and the spleen and the liver, and here exercise their poisonous influence." Thus he is prepared to explain the occurrence of fibrosis of the liver, into which the irritating microbes may easily creep, and he appears almost to suggest that the pericarditis and pleurisy might be secondary to the peritonitis with its thoracic localisation. However, let us take his conclusions; they are to this effect. 1. In these cases there is a chronic inflammation of all the serous membranes. 2. The stagnation occasioned by degeneration of the cardiac muscle leads to ascites because on account of the chronic peritonitis the peritoneal vessels offer a *locus minoris resistentiæ*. 3. The cirrhotic process in the liver so often observed under these circumstances is occasioned by the extension of inflammatory irritation from the capsule of the liver as well as by the chronic hyperæmia of the organ. 4. By the growth and contraction of this connective tissue in and about the liver the stagnation and exudation in the abdominal cavity are increased.

If now we compare the case I have here given with this case under Heidemann's care and with the others which he has collected we shall see a very close correspondence. In the former we have the co-existent evidences of inflammation in the pleura, pericardium, and peritoneum, in her also death occurs from the increasing results of cardiac failure as shown in anasarca and general dropsy, and enlargement of the abdomen was an early sign, though there is no positive information as to the exact nature of that enlargement. But it is interesting to note here that one of my colleagues who saw the case for a period of two or three weeks was inclined to believe that cirrhosis of the liver was an important feature in the case. If, however, we interpret the sequence of events in the light of Heidemann's reasoning we must suppose that twelve months before her death, when she began to be ill with swelling of the abdomen, the patient had already gone through a chronic pleurisy, pericarditis, and peritonitis of which at the age of forty-one or forty-two years she had practically no knowledge. Six months later she had apparently an acute illness, during which she was found to have physical signs suggesting effusion of fluid at the right base, and the feet were swollen. On the eighteenth day of this illness the right base was explored and no fluid was found, and the physical signs continued with but little variation, while dropsy became increasingly pronounced until her death nearly six months later. No solution of this difficulty—that is the time relations of the various lesions—is entirely satisfactory.

I propose now to deal with yet another phase of this case, and that is the occurrence of mediastinitis or matting together of the connective tissues about the large vessels of the heart. This subject of mediastinitis is one which has, perhaps, not been separately considered in much detail of late. We shall not find it indexed in many of our modern text-books on medicine, and it will be of interest to examine into its bearings on this case. "Mediastinitis" is a term which runs a danger of being used rather loosely, because what is intended to be predicated of the mediastinum may be predicated as much of the organs in the mediastinum as of the space itself. Dr. Hare's Fothergillian essay on the "Pathology, Clinical History, and Diagnosis of Affections of the Mediastinum other than those of the Heart and Aorta," gives a valuable table of published cases of mediastinitis. These are divided into suppurative and non-suppurative cases, the former being in vastly greater proportion—namely, as 115 to only 16. Of these mediastinal abscesses it is sufficient to say here that tuberculous lesions of the glands and injuries by bullet and cold steel were the most common causes. Turning now to the smaller list of non-suppurative cases, to which my own case has the closer resemblance, we find the information as to causation is meagre. In 5 only out of the 16 is a cause (as such) mentioned: three times it was pressure on the chest, once erysipelas, and once pleurisy. But 5 are described as mediastino-pericarditis, in 3 others the pericardium was involved, and in 4 the pleuræ were either thickened, adherent, or contained liquid. Hare in his summary says that the exciting causes of this trouble are very much the same as those of the suppurative form, such as traumatism in all its varieties, sudden suppression of discharges of long continuance, or in some instances suppression of the menstrual flow. The two last causes I should accept with a good deal of reserve. It is also not clear how he comes to the conclusion that of the two possible terminations of this disorder—viz., resolution and fibrous thickening of the connective tissue of the space—the former is the more common, seeing that 15 out of the 16 cases which he records were fatal. The diseases of the mediastinum occupy one of the divisions of Nothnagel's "Special Pathology and Therapeutics" now in course of issue, and that portion of the work was published in 1896. It is by Professor Dr. F. A. Hoffmann. He divides the cases into three chief groups—those arising in extension from neighbouring organs, those due to metastasis in infectious diseases, and those due to injury. He does not admit cold and suppression of menses as causes. The comparatively small section of the work devoted to mediastinitis is largely or almost entirely concerned with the suppurative forms, which it would be obviously beside the mark to consider in detail here, and practically no advance is made by him beyond what can be got from Hare, from whom, indeed, he draws largely in the matter of abscess. Osler briefly alludes to it in his "Principles and Practice of Medicine" as a part of mediastino-pericarditis, on which subject he gives the results published by Harris, who appears to find that the amounts of pericardial adhesion and of mediastinitis are apt to vary in regard to one another, and that sometimes mediastinitis may exist without the pericardium being involved at all. In this case the term "mediastino-pericarditis" hardly seems justified. The symptoms, as mentioned by Osler, are referable to adherent pericardium and changes in the shape of the heart, but none are given which can be considered as due to the mediastinitis alone. I must allow that I have not seen the original paper.

Dr. G. A. Sutherland has published an interesting case[4] in which he diagnosed chronic mediastinitis. The patient, a child aged eight years, had dulness over the sternum, prominence of the veins of the arms and neck, puffiness of the face, and duskiness in the lips, cheek, and tongue, which were no doubt rightly ascribed to enlargement of the bronchial glands; and a pleuritic rub first heard over the sternum and then more to the side showed the extension of inflammation to the pleura, and hence presumably the intermediate implication of the mediastinal connective tissue. Here, of course, it may be an open question what is the importance of the mediastinitis apart from the tuberculous lymphadenitis. In relation to the work of Heidemann already mentioned it is extremely interesting to note that in Sutherland's case ascites was an early, if not the first, sign, and throughout a prominent feature of the case, and that the possibility of cirrhosis as a cause was under discussion but was rejected in favour of compression of the inferior vena cava in consequence of the mediastinal changes. This explanation, as I have shown, would not satisfy Heidemann, who looks to chronic peritonitis as the cause of the effusion. Sutherland admits in his case the existence of chronic peritonitis; but he thinks that it is the effect, and not the cause, of the ascites, and that it is not considerable because of the abundance of the fluid and the completeness with which the fluid has been evacuated at each tapping. However, if all the lesions in this case were secondary to the tuberculisation of the bronchial glands, the case differed in its essentials considerably from my own, and the others to which I have tried to liken it.

I will now turn to the question of the diagnosis or recognition of these cases—that is, the recognition of cases of combined adhesion of the pericardium and pleura with or without peritonitis. It seems a simple thing to say that if you can recognise adherent pericardium and adherent pleura you

[4] Clinical Lecture on a Case of Chronic Mediastinitis, delivered at Paddington-green Children's Hospital on Dec. 13th, 1897, by G. A. Sutherland, M.D. Edin., M.R.C.S.Lond., THE LANCET, Jan. 8th, 1898, p. 87

Digitized by Google

can recognise the two together, but it is a matter of experience that you often cannot recognise either the one or the other. And so far as this group of cases is concerned it will be seen that in Heidemann's collected cases the thoracic conditions were partly masked by the condition of the abdomen; and in my own case one of my colleagues expressed the opinion that cirrhosis of the liver was an important factor; and, further, the right chest had been unsuccessfully explored to find fluid which was not there. After this the possibility of mediastinal changes chiefly at the lower part was made a question, to which I do not regard the mediastinitis, which was found, as being the response desired. Of course, it is well known that thickened pleura with the collapse of the lung which necessarily accompanies it will give the physical signs at the base of the chest which are too often regarded as the peculiar indications of liquid effusion. If there has been a history of pleurisy the diagnosis may be easy; if there is no such history, as in this case, and if, in addition, there are indications of disease in the heart or in the abdomen there are many other possibilities besides pleuritic adhesion and thickening which should give the physician pause.

As to adherent pericardium, in spite of the good work which has been done upon the subject it is obvious that it is often overlooked, and also that it is sometimes successfully diagnosed upon very inadequate grounds. I may especially remark here that the heart's impulse was in the normal position, that the impulse was not unduly forcible, and that the præcordial dulness did not extend beyond the left border of the sternum, so that no enlargement of the heart could be recognised, such as is present so commonly in association with adherent pericardium. Nor was there any retraction of spaces, to which, however, I attach very little importance, nor were there cardiac murmurs; nor was there, as I have already stated, any history of pericarditis or of diseases antecedent to it. The case, in respect of the pericardium no doubt falls within the group specified by Dr. John Broadbent,[5] in which the pericardial adhesion has a predominant effect upon the right heart and thus leads to its dilatation with all the other effects of stagnating circulation from this point backwards. In the absence of any lesion on the left side of the heart or of any pulmonary lesion competent to produce failure of the right ventricle the proofs of such failure would be suggestive of adherent pericardium; but obviously the difficulties of the diagnosis are very much increased if there is no history of previous acute pericarditis, and if there are pulmonary conditions, such as might result from disease of the left side and might even cause the dilatation of the right side. Here one might almost say the condition of diagnosing adherent pericardium on these lines was that adherent pleura should be diagnosed at the same time, or at any rate that the pulmonary lesion should be recognised as being neither the cause of the cardiac failure, as emphysema is of dilated right ventricle, nor the result of it, as red induration is of mitral disease. Indeed, a large part of the difficulty in recognising such cases may be said to consist in this—that the disease of one part cannot be considered on its own merits, because it is always open to the suspicion of being influenced by the disease in the others.

Then, lastly, can one take any account of the mediastinitis in the diagnosis? Can it be recognised? Can any particular symptom or group of symptoms be attributed to it? It occurs to me in this way—that from reasons of gravitation or otherwise the dropsy resulting from cardiac lesions is so constantly determined to the lower half of the body that a mediastinitis with adhesions or matting could only be suspected if the upper limbs or face or neck were quite exceptionally, or perhaps quite early, involved. This was not the case here. And yet there was one feature of the case which did turn our thoughts towards mediastinal mischief, when it was found that at the left base we had to do with solid and not liquid. And that circumstance was that three months before the patient's admission to hospital an adeno-myxoma had been removed by Mr. Lane from the left breast. However, this variety of tumour is not highly malignant, and, as a fact, it did not produce any secondary deposit in the chest as a cause of the symptoms found.

I think it will bring the subject to a fitting termination if I record another case in which a similar diagnosis may be made—that is, where pleuritic lesions are certainly present, where signs of cardiac failure are not explained by recognisable local evidence of cardiac disease, where nevertheless the pleuritic or pulmonary lesions are not such as to cause in themselves dilatation of the right ventricle, and where, finally, the implication of the pleura suggests a simultaneous and associated implication of the pericardium as the cause of the heart's incapacity.

A man, aged thirty-nine years, was admitted in February, 1898, suffering from cough, dyspnœa, and œdema of the legs. He had been in the army; he admitted having had gonorrhœa but denied that he had suffered from syphilis. His present series of illnesses began two and a half years ago. He suffered from cough, dyspnœa, and pleurisy in 1896 and was in the hospital; 24 oz. of fluid were drawn off; the liquid reaccumulated and 25 oz. were drawn off. His liver at that time reached to the umbilicus. He was again in hospital at the end of 1897 suffering from cough and dyspnœa. The breath-sounds and the voice-sounds were deficient at the left base and râles and rhonchi were present in both chests; the liver appeared to be enlarged, firm, and a little tender, but there was no ascites. The legs were very œdematous. The heart and the urine appeared to be normal. There was some rusty sputum but there were no tubercle bacilli. He got gradually better. Soon after Christmas, he again got dyspnœa and the legs began to swell and soon the abdomen, the scrotum, and even the hands slightly, followed suit. The edge of the liver was found in February, 1898, to be at the level of the umbilicus; the surface was uniform and smooth; the spleen came below the costal margin but there was no ascites. At the left base behind and in the left axilla there were dulness and diminution of breath-sounds and voice-sounds. The heart's movements could not be seen or felt; there was no retraction of spaces but there was slight epigastric pulsation; its dulness was normal and there was no murmur. Albumin was once discovered in the urine but it soon disappeared. Subsequently rubs were heard on the left side and some râles and rhonchi were always present. Three months after admission the patient was very much better; he walked about almost with comfort, but still presented inadequacy of his pulmonary bases, especially the left, bad expansion of the left chest, generally rather a quick pulse, absolutely negative character of the cardiac physical signs, the sounds being well heard, rather sharp, and approximated in quality and loudness. The liver and spleen were still large. He had not in the slightest degree the appearance of a man who had been addicted to hard drinking.

Of treatment little requires to be said; it is obvious that the most variable function is the capacity of the cardiac muscle, and practically the treatment resolves itself into that of a cardiac case by rest, diuretics, laxatives, and cardiac tonics. In the first case here recorded the treatment was absolutely of no avail. From the first and with scarce a temporary check the illness ran a downward course.

I will conclude with the following propositions:—(1) that while the combination of pleural and pericardial adhesions is by no means uncommon, a few cases are distinguished by features which render diagnosis somewhat difficult; (2) that some such cases form part of a larger group in which the peritoneum and mediastinal connective tissue are also involved in the inflammatory process; (3) that these features referred to are especially the prominence of the signs of past or present pleuritic changes and the insignificance of the local evidences of cardiac disease; (4) that such patients nevertheless do die chiefly from the incapacity of the heart, with increasing œdema and ascites, and this incapacity chiefly arises on the right side; (5) that in some cases peritonitis may have an important share in the fatal result; and (6) that in some cases ascites occurs as an early symptom and gives rise, with the passive enlargement of the liver, to suspicions of cirrhosis.

Wimpole-street, W.

[5] Adherent Pericardium, 1895, p. 43

A NEW infectious diseases hospital has just been opened at Huntingdon. Everything seems to have been done to make the building, which is the gift of Mr. J. A. Fielden, thoroughly efficient, but there is some dissatisfaction on the part of some of the ratepayers with regard to the site chosen.

PUBLIC HEALTH SERVICE IN SOMERSETSHIRE.—The recommendation of the special committee of the Somersetshire County Council advising the appointment of a county medical officer of health at a salary of £500 per annum has been deferred for further consideration.

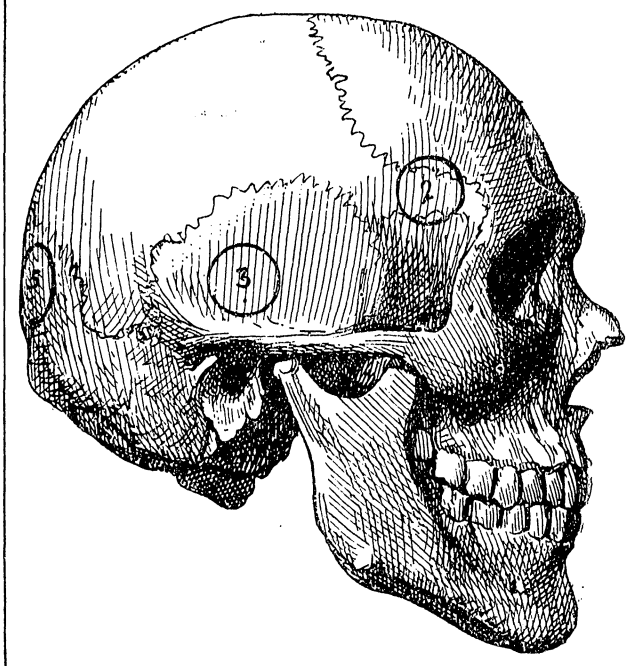
UNCOMMON CASES OF OPERATION ON THE BRAIN.

BY JAMES H. NICOLL, M.B. GLASG.,

ASSISTANT SURGEON TO THE WESTERN INFIRMARY, GLASGOW; EXTRA SURGEON TO THE CHILDREN'S HOSPITAL, GLASGOW; CONSULTING SURGEON TO THE EAR HOSPITAL, GLASGOW; CONSULTING SURGEON TO THE LUNACY BOARD, GLASGOW, ETC.



THE following three cases of operations on the brain present features somewhat out of the usual run of the ordinary intracranial operations, viz., those undertaken for abscess, sinus thrombosis, hæmatoma, and depressed fracture.

CASE 1. *Ligature of a cerebral artery for spontaneous hæmorrhage; patient nearly two years after operation in good health.*—A woman, aged sixty-two years, was sent into the Glasgow Western Infirmary by Dr. Bell Todd on Oct. 9th, 1896. Her history (as obtained from her two sons, her daughter, and a neighbour) was that she was always excitable and latterly had been much addicted to drink. One month previously she had suddenly in her house turned giddy and after staggering for a few minutes fallen unconscious. She was thought to be drunk and was placed in bed. For several days, however, she remained more or less unconscious. Then she gradually recovered, but for three weeks was in a dazed and stupid condition and "could not talk properly" (aphasia?). After that she appeared to be quite well for a week. Four days before admission, while going out, she again suddenly turned giddy and was found by a neighbour leaning against the wall of the entry. She was with difficulty got into her house and put to bed; by that time she was nearly unconscious. For three days she remained more or less unconscious and on the fourth day an acute epileptiform seizure occurred very suddenly. Dr. Bell Todd, who was hastily summoned, recognised the condition as one requiring operation and sent her at once into the infirmary. Being on duty at the time in Professor Macewen's wards I happened to see her on admission. Her condition was as follows. She was unconscious, but could be partially roused. Her pupils were equal, moderately dilated, and sluggish in reaction. There was no optic neuritis. At intervals of a few minutes there occurred violent epileptiform seizures. Each seizure began with a turning of the eyes and head to the right, followed by twitching of the right side of the head and neck. This was almost at once followed by violent twitching of the right arm and of the right lower limb. During the most severe seizures the left side of the body also became involved. The head was shaved and the patient was prepared for operation, which took place about an hour after admission. Over the motor area I removed successive portions of the skull to the extent of about 5 square inches in all. A large clot lay on the surface of the brain and there was also smart fresh hæmorrhage from the lower and anterior part of the exposed area. After removing the clot I tied the middle meningeal in the dura mater. The hæmorrhage still continuing I removed a further portion of bone in the direction from which it proceeded and exposed a cavity in the cerebral cortex of about the size of a pigeon's egg. This was lined by greyish shreddy material resembling partially bleached old blood-clot. From the lower side of this cavity an artery was spouting across the cavity. This I tied with a fine ligature. All the bone removed was replaced with the exception of one part. The wound healed rapidly, the bone uniting firmly. For several weeks she remained stupid and irritable and markedly aphasic. She ultimately was dismissed well. At present she is well in every way except in so far as that there is a gap in the skull about 1 in. square, and near it an area of skull, corresponding with that removed and replaced during the operation, which is irregular and flattened. The patient was brought before the Glasgow Medico-Chirurgical Society in November, 1897.

The artery tied appeared to be the ascending frontal branch of the middle cerebral. As to the nature of the cavity into which it was bleeding it seems an open question whether (*a*) it may have been an aneurysm which partially ruptured on the occasion of her first attack of giddiness and finally ruptured a month later, or (*b*) was produced by tearing of the brain by hæmorrhage from the ruptured artery. In either case the shreddy material on its walls appeared of much earlier date than the large clot on the brain surface, suggesting a date of origin probably contemporaneous with the date of the attack of giddiness one month before admission. The large black clot on the brain surface, on the other hand, seemed of recent origin, and in all likelihood originated at the time of the second attack of giddiness four days before admission. Whatever the exact explanation the rupture would seem to have been spontaneous. No evidence of fracture could be found nor did the shaven scalp reveal any bruising. The history also bears out this opinion.

CASE 2. *Acute symptoms of intracranial pressure due to distension of the lateral ventricle and relieved by draining; the patient at the present time well.*—A man, aged twenty-one years, on June 29th, 1897, while carrying a heavy iron casting on his shoulder tripped and fell. His forehead struck the ground, while his skull at the same time received a blow behind near the occipital protuberance from the piece of metal on his shoulder. This was followed by smart epistaxis and a condition of concussion which lasted for some hours. For a fortnight he was confined to bed suffering from headache, recurrent epistaxis, and giddiness. Over the junction of the nasal and frontal bones anteriorly, and over the occipital bone posteriorly, there was tenderness and in the latter situation there was some swelling for a time. At the end of the fortnight he gradually

FIG. 1.

within a few days regained his normal condition, and for about two months was fairly well except that he occasionally felt giddy when stooping and had occasional epistaxis. On Oct. 15th, three and a half months after the accident, his condition changed. He suffered from severe pain in the right frontal region, marked giddiness, and a tendency to frequent vomiting. These symptoms increased in severity till Oct. 25th when I saw him in consultation with Dr. John Barr Stevens. At that time his condition was, briefly, as follows. His temperature was practically normal and his pulse was 62; there was severe and constant pain in the right frontal region. The slightest movement, even turning the head on the pillow, produced instant giddiness and frequently resulted in vomiting. The patient appeared to be dull and lay very still, possibly more from the desire to avoid the giddiness and vomiting consequent on any exertion than from commencing coma, though Dr. Stevens, who had full opportunity of observing his condition, is of opinion that at this time there was a tendency to stupor and commencing coma. His speech was slow and hesitating. There was no paresis or spasm of the face, arms, or legs. There was no optic neuritis. His nasal bones were loose and "rocking" on the frontal bone. On Oct. 28th, his condition being

Digitized by Google

unchanged except that there was distinctly more stupor, I decided to explore the interior of the skull for the source of pressure. There being present only *general* symptoms of intracranial pressure, without any definite *localising* evidence, I was guided in my decision to explore the frontal region by the presence of pain there and by the loose condition of the nasal bones. Discs of bone 1 in. in diameter were removed from the sites marked (1) and (2) in Fig. 1. The dura mater in both places presented no bulging and pulsated normally. In both sites the dura mater was incised and the brain explored to the depth of 1½ in. by means of Macewen's cannula with negative result. The effect of the operation was a slight diminution of pain and giddiness for a few days, after which the patient relapsed into his former condition with deepening stupor. On Nov. 9th I again saw him with Mr. W. G. Stevens and Dr. J. B. Stevens and decided to explore further. I removed a 1 in. disc of bone in site 3 in Fig. 1 and found the dura mater over the temporo-sphenoidal lobe bulging and pulseless. On incising it the subjacent cortex appeared to be pale, pulseless, and bulging. Exploration with the cannula in three different directions to the extent of 1 in. and 1½ in. gave no result, but on pushing the cannula in the direction of the ventricle it entered that cavity and evacuated a considerable quantity of fluid, the amount of which, however, could not be ascertained. With the object of discovering the possible source of this distension of the ventricle, in the shape of abscess, hæmatoma, or tumour pressing on the veins of Galen, I removed 1 in. discs of bone in site 4 over the cerebellum and site 5 over the occipital lobe and explored both cerebellum and occipital lobe with the cannula. The result was negative. From that date the patient made an uninterrupted recovery and is now well. He was shown to the Glasgow Medico-Chirurgical Society in March, 1898.

Three things have induced me to think the case of sufficient interest for publication. 1. The diagnosis. It is not uncommon for acute distension of one or both lateral ventricles to follow from blocking of the veins of Galen, the result of the presence in the cerebellum or occipital lobe of abscess, hæmatoma, or tumour. In this case, however, both the subsequent negative exploration of the cerebellum and occipital lobe and the patient's perfect recovery go to exclude that possibility. Amongst the various possible explanations of the distension of the ventricle perhaps the most probable in this case is that the vein of Galen draining the right ventricle was obstructed by thrombosis originating in some way from the injury received at the time of the fall. 2. The extent of the cerebral exploration carried out. Though not the most extensive exploration of the encephalon I have carried out it is the most extensive exploration of one hemisphere I have yet had to undertake, and when it is recollected that from each of the five trephine apertures the cannula was passed in 2 or 3 directions into the brain for distances varying from 1 in. to 2 in. it will be seen that the interference with the brain was considerable. As consulting surgeon to the Glasgow Ear Hospital, when on duty in Professor Macewen's wards in the Western Infirmary, and in private practice I have frequently had occasion to explore the temporo-sphenoidal lobe and cerebellum on one side and in some cases, in addition, the occipital lobe. In several cases which have been under my care I have explored one or other, or several, of these sites on both sides. In this case, however, there has been added the not very common exploration of the frontal lobe. Practice has advanced with great rapidity of late years in cerebral cases. There must be a limit to interference with the brain. With a knowledge of the anatomy of the brain and strict asepsis, however, it is not yet clear where the limit of successful interference with the brain is to be placed. 3. The method of dealing with the discs of bone removed. Much has been written, and opinions widely differ, as to the best method of dealing with bone removed from the skull in the matter of providing the most efficient protecting covering for the brain. The principal methods advocated are: (*a*) leaving the bone removed unreplaced on the ground that if replaced it either necroses or undergoes absorption. In this method the brain is protected by the dura mater, pericranium, and scalp fused together. (*b*) Breaking up the discs removed into small portions and implanting these on the sutured dura mater in the gap. In this method these portions of bone are said to grow and firmly fill the gap. (*c*) Splitting the disc into two lamellæ and replacing one only. The supporters of this method assert that the thin lamella of half the thickness of the disc is more easily vascularised and therefore less likely to necrose than the thicker plate formed of the entire disc. (*d*) Replacing the entire disc. In this case I followed the method I have always practised—viz., replacing the entire disc. In this case the discs were not even kept in warm solution. They were laid between folds of dry sterilised gauze till the operation was over, then replaced, and the scalp was sutured over them. The wounds healed by first intention under the original dressing. At the present time all five discs are, four months after operation, firmly united *in situ*.

With the two objections urged against replacing the entire discs—viz., the risks of necrosis during healing and of remote absorption—it is not easy to deal without some knowledge of the circumstances in which these untoward results have occurred. I have not seen absorption occur, and I have lately inspected three cases where the entire disc had been replaced ten, seven, and six years ago respectively. In none of these can I detect any evidence of absorption. It is not easy to follow up one's cases, however, more especially hospital cases, and in the meantime, until I have been able to extend my observations, I should wish to reserve final judgment. Whether subsequent absorption of the disc, granting it to be at all common, constitutes any argument against replacing it is another matter. It would appear that what remains of the absorbed disc uniting with the fused dura mater and pericranium should tend to increase the protecting covering of the brain. Necrosis of the replaced disc is also an occurrence of which I have had no personal experience. In a now very considerable number of cases I have not, if I may trust my notes and memory, seen it once. In the records of cases in which it has occurred and in the observations of certain writers there is evidence that the main, if not the only, cause of necrosis of the disc is sepsis. Should anything be permitted to interfere with the strictly aseptic condition of such a wound it could hardly be matter for surprise should necrosis of the disc result.

CASE 3. *Malignant tumour of the brain originating in the middle ear; symptoms simulating temporo-sphenoidal abscess; removal of intracranial portion of the tumour, with relief of pressure symptoms; death two and a half months after operation.*—On May 18th, 1897, I saw the patient, a boy, aged twelve and a half years, with, and at the request of, Dr. Barr, senior aural surgeon of the Glasgow Ear Hospital. The symptoms were persistent vomiting, pain on the right side of the head, subnormal temperature, slow pulse, drowsiness, stupor, and steadily developing coma, right optic neuritis, dilatation of the right pupil, paralysis of the right third and fourth nerves, and paresis of the left sixth nerve. Some time previously the patient had been brought to Dr. Barr suffering from paroxysmal pain, deafness, and purulent discharge in connexion with the right ear. Dr. Barr had found the middle ear occupied by tough granulation-like tissue, and had opened the mastoid cavities and thoroughly cleared both these and the tympanum of this tissue. Portions of this tissue were under examination when the serious intracranial symptoms above detailed developed and Dr. Barr requested my coöperation. We agreed that the symptoms indicated a lesion in the temporo-sphenoidal lobe. As to the nature of that lesion we were also at one in thinking it probably an abscess and not a tumour and this for the following reasons: (*a*) the boy had, and had had for three months, the most common exciting cause of intracranial abscess in the form of a purulent otitis; (*b*) the rapidity and progressiveness of the development of the symptoms of intracranial lesion, a matter of five or six days in all; and (*c*) apart from these considerations the symptoms themselves afforded no sufficient evidence on which to decide between the two probabilities—abscess and tumour. That being so it was natural to think it more probable that the lesion was the common one, abscess, and not a rarity in the shape of a malignant tumour causing both aural and intracranial symptoms. Later in the day I operated along with Dr. Barr and assisted by Mr. F. Adams and Dr. J. G. Connal, assistant surgeons to the Ear Hospital. In the first place I still further enlarged the very free mastoid opening previously made by Dr. Barr so as to freely open the bony channel of the sigmoid sinus. This was largely occupied by a firm greyish granulation-like tissue. The operation had then lasted about ten minutes. At this point the patient's respiration gradually became shallow and finally ceased. The pulse remained perfectly good. The patient was evidently in a condition of apnœa from cerebral pressure. Artificial respiration was begun. No stimulant

was given nor was the foot of the table raised. After some minutes I performed tracheotomy on the suggestion of the chloroformist, Dr. Connal, who found this an aid to artificial respiration. For over one hour the patient's condition remained unchanged. So long as artificial respiration was kept up the pulse and colour remained good, but on stopping the artificial respiration from time to time there was not the faintest attempt at spontaneous breathing. It was then decided to open the skull at all hazards and explore the temporo-sphenoidal lobe. This I did while artificial respiration was still being carried on. On removing a large trephine crown of bone, about 1½ in., directly over the external auditory meatus the dura mater bulged markedly. In the dura mater I made a crucial incision. The cerebral cortex bulged at once in the opening, evidently under great pressure. At this point, one hour and ten minutes after the breathing had failed, the first faint effort at spontaneous respiration occurred. I explored the temporo-sphenoidal lobe with the trocar. No pus was got, but at a short distance under the cortex a hardish mass was detected. I divided the cortex and displaced it to either side and exposed a firm greyish mass of tissue similar in appearance to that which had been exposed in the groove of the sigmoid sinus. With a small elevator a portion of this was removed. The patient was now breathing regularly and there had occurred a marked contraction of the previously dilated right pupil. I enlarged the aperture in the skull by means of gouge forceps and removed a considerable portion of the intracranial tumour. This was readily distinguished by the sense of touch from the soft brain around. After evacuating the larger part of the then intracranial portion of the growth it became clear that the tumour sprang from and widely permeated the petrous bone. I therefore gave up the attempt to remove more and applied an aseptic packing and dressing. By this time the patient, to whom no chloroform had been administered from the time apnœa set in, was moaning and struggling to get at our hands working at his head. For some days the symptoms were relieved, the headache, drowsiness, and vomiting having ceased. After that time, however, the headache returned—as formerly, more marked in the right side—and the right pupil was again dilated. At the end of a fortnight optic neuritis occurred in the left eye, rapidly followed by atrophy and blindness. Soon after this the left side of the face became paralysed and this was followed by paresis of the left arm. During the two and a half months he survived the operation there was no return of the semi-comatose condition developing before the operation and on only one occasion was there any return of the vomiting. On two occasions towards the end of the first month I shaved off portions of the growth which had fungated through the large cranial opening and were giving rise to hæmorrhage. On June 18th, a month after the operation, he was removed home to Saltcoats and the further report is by Dr. Campbell, whose patient he was. Dr. Campbell notes on June 19th: "Hearing, taste, and smell perfect. Intellect clear. No pain. Temperature normal. Complete blindness. Paralysis of left side of face and of left arm." For the following six weeks his condition varied little, except that the old pain in the head occasionally returned, and on one occasion he had a recurrence of the vomiting. About a week before death he became gradually completely deaf. Four days before death drowsiness returned and gradually merged into coma with a steadily rising temperature, which just before death, on August 2nd, reached 107°. The specimen (of which photographs are reproduced) was exhibited in the Museum of the British Medical Association meeting in Edinburgh, July, 1898.

Digitized by Google

The two points of interest in the case are—(1) the apnœa (probably produced by the action of the chloroform on a brain the site of steadily developing pressure coma) and the almost dramatic immediate relief of both apnœa and coma

of opinion amongst the pathologists consulted, several favouring soft carcinoma and several alveolar sarcoma. The accompanying illustrations (Figs. 2, 3, 4, and 5) give a fair idea of the size and structure of the tumour.

Glasgow.

NORTH-EASTERN HOSPITAL FOR CHILDREN, SHOREDITCH.—A complete Roentgen rays apparatus has been presented to the North-Eastern Hospital for Children, Hackney-road, Shoreditch, by the Duke of Newcastle, who is a member of the committee. The apparatus, which was made by Mr. J. Le Couteur, throws an 18-in. spark, and is in every way an efficient adjunct to the clinical work of the hospital.

FREEMASONRY.—At the regular monthly meeting of the Chaucer Lodge, No. 1540, held at the Bridge House Hotel, London Bridge, on Monday, Oct. 24th, Bro. Heinrich Oppenheimer, M.D. Heidelberg, M.R.C.P. Lond., was duly installed W.M. The banquet which followed the ceremony was largely attended and an enjoyable evening was spent.

SUMMARY OF GUNSHOT WOUND CASES TREATED IN NO. 2 NATIVE GENERAL HOSPITAL AT RAWAL PINDI.

BY CAPTAIN D. M. MOIR, I.M.S., M.B., C.M. EDIN.,
REGISTRAR NO. 2 NATIVE GENERAL HOSPITAL.

THIS hospital of 500 beds was mobilised for about a period of six and a half months, from the middle of October, 1897, to the end of April, 1898. It received sick and wounded from the field hospitals in the Tirah expedition, who were transferred through the native general hospitals at Kohat or Naoshera. Altogether 2946 patients were treated, of whom 1453 were fighting men and 1493 followers. Of this number only 309 were surgical cases, 233 being fighting men and 76 followers. There were no deaths among the surgical cases, whereas the mortality from disease amongst the remaining 2637 patients was 89, 11 fighting men and 78 followers died. The nature of the surgical cases was as follows:—

Injuries.*	Fighting men.	Followers.	Total.
(*g*) Burns and scalds	1	5	6
(*a*) Contusions	10	12	22
(*e*) Wounds	5	19	24
(*d*) Gunshot wounds	193	28	221
(*b*) Sprains	11	2	13
(*p*) Dislocations	1	—	1
(*k*) Fracture of skull	1	—	1
(*j*) Abrasions	6	1	7
(*n*) Fracture of other bones ...	5	9	14
Total	233	76	309

* The classification used in Army Hospital Forms 80 and 81 is here adopted.

This paper deals with the 193 cases of gunshot wounds amongst native officers, non-commissioned officers, and men. It was not an easy matter to ascertain accurately the locality or engagement at which the men were wounded, partly owing to their vague replies, but chiefly on account of this information not being supplied in the papers accompanying them. However, as far as could be gathered the following are the places at which the wounds were inflicted:—Dargai 50, Tirah (vague) 55, Maidan in Tirah 20, Kuki Khel in Tirah 2, Tabai in Tirah 2, Bagh 12, Charbagh 1, Kharappa 8, Bara Valley 7, Saransar 6, Waran 5, Dwatoi 5, Mastura 3, Shinawari 2; Asmar, Shabkadr, Gulistan, Samana, Sampagha, Kai, Karmana Dara, Sadda, each 1. Also 1 man was wounded near Kohat and another near Khusalgarh, and 5 were "unknown." Particulars as to the nature of the projectile or of the weapon used could be obtained in only a small number of the cases. All that inquiry and examination could elicit was that 16 of the wounds were caused by the old-fashioned round or spherical bullet, 12 by the Martini-Henry, 11 by the Lee-Metford, 11 by the Snider, 1 by a cavalry carbine, and in the remaining 142 cases no reliable data could be got.

Medical officers at the front and on the lines of communication have their hands full; but still it would not increase their work much, and it would add very much to the interest of the cases, if printed forms were supplied in which they might jot down the following data while events were fresh in their minds. The forms might contain such headings as: (1) place or action at which wound was received; (2) nature of weapon or projectile; (3) nature of injury; (4) approximate distance at which the shot was fired, also the direction from in front, behind, above, &c.; (5) attitude of patient at the time he was struck, whether he was running, standing, lying down, &c.; and (6) any other facts of interest. Of course, such information could not be obtained in all instances, but it would be forthcoming in many cases, and thus valuable knowledge as to the effects of different projectiles at varying ranges in actual warfare could be collected.

The Gurkha and Sikh regiments supplied the greatest number of wounded; no less than 157 out of 193 belonged

Digitized by Google

to these corps. There were 101 wounded Gurkhas from the 2nd Battalion 1st Regiment, 1st Battalion 2nd Regiment, 2nd Battalion 2nd Regiment, 1st Battalion 3rd Regiment, 2nd Battalion 4th Regiment, 1st Battalion 5th Regiment, and 2nd Battalion 5th Regiment. The 1st Battalion 2nd Gurkhas and the 1st Battalion 3rd Gurkhas suffered most severely, there being 49 from the former and 35 from the latter. The 3rd, 15th, and 36th Sikhs furnished 56 wounded, the last two corps in nearly equal numbers—24 and 29. Native cavalry regiments and mountain batteries each added 5 to the total of wounded and the remaining 26 came from the Bombay Sappers and Miners, 28th Bombay Pioneers, 21st Madras Pioneers, Jhind Infantry, 2nd Punjaub Infantry, 12th B. I., and 22nd Punjaub Infantry.

LEE-METFORD BULLET WOUNDS.

The cases of wounds from the Lee-Metford bullet[1] make rather an interesting series and they tend to confirm previous experience regarding its relative harmlessness (so long as a bone is not struck) as compared with the damage done by most other projectiles used in modern warfare.

CASE 71. *Gunshot wound of the chest, IV., 5.*—The patient (15th Sikhs) was wounded in Tirah on Nov. 9th, 1897, by a Lee-Metford bullet fired from behind him. The bullet entered on the left side of the back of the chest just below the lower angle of the scapula and internal to it through the seventh costal space. It traversed the lung and emerged in front through the second left costal space 3 in. above the nipple and 1 in. internal to the left mammary line. He fell down immediately on being hit and there was considerable hæmorrhage from the wounds and from the mouth. Air also escaped from the wounds and there was emphysema of the tissues surrounding them. The treatment consisted in antiseptic dressing and strapping of the chest, with the free administration of opium. The wounds, which were both very small, round, and of equal size, healed up in a fortnight. He was received at Rawal Pindi on Dec. 1st with the wounds soundly healed, but he complained of occasional pain in the chest on the side affected and also of a slight cough. No marked dulness could be elicited on percussion and the breath sounds were normal on auscultation. On Dec. 24th he was given three and a half months' sick leave. This man had a marvellous escape because, though the bullet entered below the level of the root of the lung and its main vessels, yet it traversed the whole thickness of the lung and emerged in close proximity to the great vessels at the base of the heart.

CASE 48. *Gunshot wound, XV., miscellaneous (pelvis).*—The patient (1st Battalion 3rd Gurkhas) was wounded at Dargai on Oct. 18th, 1897, by a Lee-Metford bullet, which struck him in the cleft between the nates over the lower end of the sacrum and passed forwards and outwards to emerge a little above and in front of the great trochanter of the right femur, its track being quite 10 in. long. The impact of the bullet knocked him down and he was carried to camp in a dhoolie. In his medical certificate it was stated that the right os innominatum was fractured, but all evidence of this was gone when he arrived here on Nov. 14th. The scars of the apertures of entrance and exit were very small and both were about the same in size and shape. In spite of the long 10 in. track the wound was healed in a fortnight. He was discharged to duty at his regimental depôt on Nov. 29th.

CASE 28. *Gunshot wound of the neck, III., 2, with injury to the cervico-brachial plexus.*—The patient (15th Sikhs) was wounded on Oct. 18th, 1897, at Dargai, by a Lee-Metford bullet which hit him on the back of the neck 1 in. to the left of the middle line on a level with the upper and inner angle of the scapula. It passed forwards and outwards, emerging about 2 in. above the middle of the left clavicle. When admitted here on Nov. 9th both wounds were healed and the resulting scars were very small; that of the exit wound was the smaller of the two. In this case also the wound was healed in a couple of weeks. He complained, however, of pains shooting down his left arm and up the side of his neck and head, the pain being worst at night. It is probable that the bullet in its passage through the neck injured some of the nerves. He was discharged to his depôt on Nov. 29th, but still complained of pain in his neck and arm.

CASE 133. *Gunshot wound, VII., perineum, &c.*—The patient (28th Bombay Pioneers) was wounded at Dwatoi on Dec. 9th, 1897, by a Lee-Metford bullet, which entered immediately to the left of the root of the penis and emerged at the outer side of the right buttock an inch and a half above the fold of the nates, traversing the perineum. Apparently neither the urethra nor the bladder were injured, nor was the pelvis fractured. On Dec. 21st, when he was admitted here on transfer, the wound was completely healed and he was discharged to duty at his depôt three days later. In this case an extensive wound, very liable to septic contamination from its situation, was healed in less than two weeks.

CASE 182. *Gunshot wound in the back, VI., 1.*—The patient (15th Sikhs) was wounded on Nov. 9th, 1897, at Maidan by a Lee-Metford bullet while he was lying down. It entered the right side of the back a little below the level of the iliac crest and came out about the corresponding place on the left side, having a long course through the left tissues without any apparent injury to bone. An abscess formed later and pus was evacuated through an incision midway between the two wounds. On admission here (Jan. 22nd, 1898) all three wounds were nearly healed. Early in the first week of February the wounds were healed, but he had been suffering much from malarial fever and debility. On Feb. 15th he was sufficiently well to be sent on six months' sick leave to his home.

CASE 134. *Gunshot wound in the lower extremity, IX., 1.*—The patient (28th Bombay Pioneers) was wounded in Tirah on Dec. 10th, 1897, by a Lee-Metford bullet which entered the inner aspect of his right thigh at the junction of its middle and lower thirds. It passed upwards and backwards through the whole thickness of the thigh and escaped 2 in. below the fold of the nates. When transferred here on Dec. 21st both wounds were almost healed and were very small and round. There had been no suppuration nor had there been any injury to bone or important structures. The wound was quite healed within a fortnight of its infliction and the patient was discharged to duty at his depôt three days after admission.

CASE 142. *Gunshot wound in the lower extremity, IX., 1.*—The patient (36th Sikhs) was wounded in the retirement from Bagh on Dec. 12th, 1897. A Lee-Metford bullet struck the front of his left thigh 8 in. below the anterior superior iliac spine, passed to the inner side of the femur, and came out at the same level on the back of the limb without injuring any important structure. On admission here (Dec. 21st) both wounds were very small, round, punched out and were healing well. By Jan. 17th, 1898, they were firmly healed.

CASE 155. *Gunshot wound in the lower extremity, IX., 1.*—The patient (1st Battalion 3rd Gurkhas) was wounded in the left leg on Dec. 13th, 1897, in Tirah. A Lee-Metford bullet entered a little above the middle of the leg, 1 in. external to the edge of the tibia, and passing backwards and downwards it emerged in the middle of the calf. On admission here (Dec. 21st) the wounds were very small and were healing satisfactorily. By Jan. 11th, 1898, the wound was soundly healed and the man was discharged to duty at his depôt next day.

CASE 145. *Gunshot wound in the upper extremity, VIII., 1.*—The patient (36th Sikhs) was wounded in Tirah on Dec. 11th, 1897, by a Lee-Metford bullet, which struck the right arm just in front of the deltoid insertion, passed to the outer side of the humerus and came out behind at the same level. On admission here (Dec. 21st) both wounds were small, round, clean, punched out and healing well. By Jan. 4th, 1898, they were healed thoroughly.

CASE 146. *Gunshot wound in the upper extremity, VIII., 1.*—The patient (Jhind Infantry) was wounded at Dwatoi on Dec. 10th, 1897, by a Lee-Metford bullet fired from behind him. It entered at the back of the right arm about 1 in. below the deltoid insertion, passed upwards, and came out just below the acromion process without injuring bone or joint. On admission here (Dec. 21st) both wounds were quite healed—i.e., within twelve days of the injury. His head must have been turned to one side when he was hit, otherwise it could scarcely have escaped being struck.

CASE 166. *Gunshot wound in the upper extremity, VI.I., 1.*—The patient (1st Battalion 3rd Gurkhas) was wounded in Tirah on Dec. 18th, 1897, by a Lee-Metford

[1] I have condensed the following abstracts of cases from the case-books of medical officers in charge of the sections of the hospital. Accordingly, I am indebted to Captain W. H. Gray, Captain H. B. Melville, Captain S. H. Burnett, Captain B. G. Seton, Captain T. W. A. Fullerton, Captain J. S. S. Lumsden, and Captain H. Burden, also to Lieutenant C. B. Harrison and Lieutenant J. M. Woolley, for their notes. The classification adopted is that of Army Form A 7, which needs revision, as I pointed out in an article which appeared in the Indian Medical Gazette for June, 1898.

Digitized by Google

bullet, which struck the right forearm 3 in. above the wrist. It entered over the inner edge of the ulna, passed in front of both bones, and emerged on the outer side of the radius 2 in. above the wrist, thus crossing the point of the forearm obliquely without injuring the bones. On admission here (Dec. 21st) both wounds were merely small round ulcers. On Jan. 1st, 1898, there was loss of power in the hand and the movements of the fingers were defective both as regards flexion and extension. Although the power of opposition of the thumb was unimpaired, yet he could not hold or lift anything firmly in his hand. On March 12th there was some improvement, but the hand was still weak and movements were impaired. On the 31st prognosis was unfavourable, so he was sent to his depôt to appear before an invaliding board.

While describing these 11 cases of Lee-Metford bullet wounds I may as well complete the dozen by mentioning one which came under my treatment from the beginning at the Followers' Cantonment Hospital, Rawal Pindi. It is interesting in that it tends to show that a Lee-Metford bullet had not apparently sufficient force to perforate completely both the forearm and leg of a thin and feeble native at some distance less than 2000 yards. It is also an example of wounds healing in a couple of weeks or less.

A man, aged thirty years (a grass-cutter), was shot by a Lee-Metford bullet while squatting and cutting grass behind one of the rifle ranges when firing was going on. The bullet struck his naked arm and leg, which were thin and poorly nourished. It passed through the fleshy part of the back of his right forearm and then entered the outer side of his right calf and lodged just under the skin on the inner side. This happened on March 29th, 1898. He was brought to hospital the same day and the bullet was at once extracted through a skin incision over it. On admission the man was not suffering from shock and he was able to stand, though he did not attempt to walk then. However, he was caught walking about within a week of the accident. The wounds in the forearm were healed on the ninth (exit) and tenth (entrance) days. The incision in the leg was healed on the eleventh day and the wound of entrance healed on the sixteenth day, this last having been retarded by slight suppuration. In the opinion of the officer commanding the regiment and from the evidence at a court of inquiry it would appear that the grass-cutter was hit about half a mile behind the butts and that the company at practice began firing at 1100 yards and advanced up the range towards the butt. Therefore the shot may have been fired at a distance much less than 1100 yards but allowing the maximum distance of 1100 yards from the firing point to the butt and of 880 yards behind the target, yet the total comes to less than 2000 yards and the bullet had not had sufficient force to perforate completely the arm and leg of a poorly-developed native. It may be objected, however, that the shot was a ricochet and that part of the force and velocity were expended on some other object before the man was struck. Against this is the fact that the bullet was absolutely unaltered in shape—it had not the least scratch, flattening, or indentation on its surface.

WOUNDS FROM SPHERICAL BULLETS.

Passing next to consider the effects of the old-fashioned round ball we find they make a sharp contrast with those of the Lee-Metford as detailed above.

Effects of spherical bullets.—(1) Mostly lodged, requiring an operation for extraction; (2) suppuration usual from the bruising of the tissues and the introduction of septic foreign bodies, hence sinuses and slow healing; (3) fractures and injuries of important structures common; and (4) course of bullet tract often tortuous.

Effects of Lee-Metford bullets.—(1) Did not lodge (except in the last case), hence much less subsequent manipulation of the wounds; (2) much less tissue injured, cloth, &c., not carried into the wound, hence rapid healing often without suppuration; (3) bones and important structures escaped injury in a wonderful way; and (4) course of bullet track usually straight.

CASE 49. *Gunshot wound in the upper extremity, VIII., 2.*—The patient (1st Battalion 2nd Gurkhas) was wounded at Dargai on Oct. 20th, 1897, by a spherical bullet which struck him on the deltoid muscle just above the right shoulder joint, and passed inwards and forwards under the clavicle, lodging about 4 in. or 5 in. from the wound of entrance. It fractured a portion of the outer end of the clavicle and also the acromion at the acromio-clavicular joint. Some pieces of bone were extracted shortly after he was injured. When he was admitted here on transfer (Nov. 14th) he was suffering great pain in the shoulder and neck; there was a copious discharge of thick pus from the wound and the temperature ranged between 100°F. in the morning and 102° in the evening. On Nov. 18th under chloroform the wound was enlarged and explored and a spherical bullet was felt lying in the neck 4½ in. from the entrance, but it could not be extracted until a counter-opening was made just above the supra-spinous fossa. This incision served the double purpose of allowing of the removal of the projectile and also of providing free drainage. The capsule of the shoulder-joint was not injured. The bullet was a round one, about five-eighths of an inch in diameter, weighing half an ounce On Dec. 12th the counter opening had healed. On Jan. 20th, 1898, the primary wound was closed. On the 27th the patient was sent home on three and a half months' sick leave.

CASE 83. *Gunshot wound in the upper extremity, VIII., 2.*—The patient (1st Battalion 2nd Gurkhas) was wounded at Dargai on Oct. 20th, 1897, by a spherical bullet fired from above him. The wound of entrance was immediately over the tip of the right acromion process. On admission here (Nov. 9th) there was considerable antero-posterior thickening over the head of the humerus, with fulness in the axilla and induration of the soft parts of the upper half of the arm. This led to a suspicion that the bullet had entered the shoulder joint; but when the patient was put under chloroform on the 22nd it was found that the bullet had fractured the spine of the scapula and was lodged in the infra-spinous fossa. The aperture in the spine of the scapula had to be enlarged in order to admit of the removal of the bullet as well as of a piece of khaki cloth (from his coat) which was one inch long, half an inch broad, and in two layers. In spite of antiseptic precautions and good drainage profuse and prolonged suppuration supervened. It was not till April 9th, 1898, that he was made over to his regiment, at which time there was a small sinus less than an inch long and also a good deal of stiffness of the joint from extra-capsular adhesions.

CASE 39. *Gunshot wound in the upper extremity, VIII., 1.*—The patient (1st Battalion 2nd Gurkhas) was wounded at Dargai by a spherical bullet. On admission here on Nov. 12th, 1897, there was a small wound at the posterior and lower margin of the right deltoid only half an inch deep. There was no wound of exit and there were no signs of the bullet. By the 22nd the wound was healed, but a day or two later he complained of pain on raising the arm. On the 26th a hard lump could be felt at the edge of the latissimus dorsi. Cocaine solution was injected, the lump was cut down on, and a round bullet was readily shelled out. Evidently this bullet had altered its position and come nearer the surface while he was under treatment, because no sign of it was perceptible on manipulation when he was admitted or during most of the time he was in hospital.

CASE 8. *Gunshot wound in the upper extremity, VIII., 1.*—The patient (1st Battalion 2nd Gurkhas) was wounded at Dargai by a spherical bullet which grazed his left upper arm, entering over the inner side of the biceps. It passed under the skin and emerged 2 in. lower down. The wound was healing well on his admission here (Nov. 3rd, 1897) and he was fit to be discharged to duty at his depôt ten days later.

CASE 82. *Gunshot wound in the upper extremity, VIII., 4, ulna.*—The patient (1st Battalion 3rd Gurkhas) was wounded at Shinawari on Nov. 18th, 1897, by a spherical bullet, which struck the back of his right forearm midway between the elbow and the wrist, fracturing the ulna, and then lodged. The ball was extracted the same day through an incision on the front of the forearm 1 in. below the bend of the elbow. No bone was then removed and no fragments have since come away. The elbow joint was not injured, but the movements of pronation and supination were somewhat impaired. On admission here (Dec. 3rd) the wounds were merely small ulcers, but a sinus persisted, discharging a thin watery fluid, and a fragment of dead bone was suspected. On Jan. 18th, 1898, under chloroform the sinus was slit up and a small sequestrum was removed as well as half-a-dozen strands of wool from a cardigan jacket. On March 2nd prehensile power and movement had greatly improved. The wound healed some time ago. The patient was sent on six months' sick leave.

CASE 83. *Gunshot wound in the neck, III., 1; upper extremity, VIII, 6.*—The patient (36th Sikhs) was wounded in Tirah on Nov. 16th, 1897, by two spherical bullets. One entered the right side of the root of his neck and lodged

Digitized by Google

It was removed the next day by an incision 4 in. behind the point of entrance. The other bullet struck the palmar aspect of the terminal phalanx of the right thumb, passed upwards and emerged beyond the joint between the first and second phalanges, fracturing the bone and injuring the joint. Some fragments of the terminal phalanx were removed soon after the injury. On arrival here (Dec. 3rd) both wounds were nearly healed, but the thumb was rather stiff. On Dec. 27th he was sent on three months' sick leave.

CASE 51. *Gunshot wound in the face, II., 2.*—The patient (Rocket Section, 5th Mountain Battery) was wounded at the Sampagha Pass on Oct. 29th, 1897, by a spherical bullet, which struck him in the hollow between the chin and the lower lip and lodged in the body of the lower jaw. One tooth in the upper jaw was broken across and three teeth in the lower jaw were loosened. The bullet was removed the same day. On transfer here (Nov. 14th) the wound was nearly healed and he was discharged to duty at his depôt on Dec. 1st.

CASE 117. *Gunshot wound in the face, II., 3; right eyeball; neck, III., 1.; upper extremity, VIII., 1.*—The patient (1st Battalion 5th Gurkhas) was wounded near Sadda on Nov. 7th, 1897, by a spherical bullet while he was in a kneeling attitude. The bullet was fired from above and first hit his right eye, completely disorganising it. Next the ball struck his right shoulder over the acromion process and was diverted at an acute angle, passing under the muscles to emerge over the spinous process of the last cervical vertebra. The bullet was found in his clothes. An operation was performed to remove the remains of the injured eye. On admission here (Dec. 7th) all his wounds were healed and he was discharged to his depôt four days later.

CASE 110. *Gunshot wound in the abdomen, V., 2; fracture of pelvis.*—The patient (15th Sikhs) was wounded at Maidan on Nov. 16th, 1897. The wound of entrance was in the right hip 3 in. below the crest of the ilium and the bullet lodged in the abdominal parietes. It was removed through an incision 2 in. above the middle of Poupart's ligament and proved to be of the ordinary spherical type. The abdominal cavity was not penetrated. On admission here (Dec. 2nd) the extraction wound was healed and the wound of entrance appeared to be closing. On the 26th there was a purulent discharge from the sinus of the entrance wound, which was 2 in. long. On the 30th bare bone was felt with the probe at a depth of 3 in. and the probe passed completely through the ilium. Apparently the bullet must have pierced the right iliac bone and then must have passed under or through the iliacus muscle without penetrating the peritoneal cavity. On Feb. 1st, 1898, the wound had quite healed and three days later he was sent on four months' sick leave.

CASE 5. *Gunshot wound in the back, VI., 1.*—The patient (1st Battalion 2nd Gurkhas) was wounded by a spherical bullet at Dargai on Oct. 20th, 1897. It lodged in his back and was extracted shortly afterwards. He was struck on the right side of the back a little above the waist and the bullet track passed obliquely downwards to the left for 3 in. deeply amongst the muscles of his back. On arrival here (Nov. 3rd) the wound was healed.

CASE 151. *Gunshot wound in the back VI., 1.*—The patient (1st Battalion 3rd Gurkhas) was wounded in the Bara Valley on Dec. 13th, 1897, by a spherical bullet which entered behind the left shoulder near the posterior superior angle of the scapula and passed out 1 in. above the junction of the upper and middle thirds of the axillary border of that bone, which was not injured. On arrival here (Dec. 21st) the wounds were almost healed, so he was discharged to duty at his depôt three days later.

CASE 112. *Gunshot wound in the lower extremity, IX., 1.*—The patient (2nd Battalion 4th Gurkhas) was wounded at Kharappa on Oct. 28th, 1897, by a spherical bullet, which lodged in the left buttock and was extracted through the original wound. On admission here (Dec. 7th) there was merely an ulcer 2 in. long, by half an inch broad, which soon healed.

CASE 98. *Gunshot wound in the lower extremities, IX., 1.*—The patient (36th Sikhs) was wounded in Tirah on Nov. 16th, 1897. One bullet struck him on the front of the right leg about 5 in. above the ankle joint. It lodged between the bones and was extracted the same evening. Another bullet struck him on the back of the left thigh just below the fold of the buttock and lodged. It was also extracted the same evening. Both bullets were of the ordinary spherical pattern. On Dec. 4th he was received on transfer. On the 11th the wound in the thigh healed. On the 20th the wound in the leg healed. On the 29th he was sent on three months' sick leave.

CASE 169. *Gunshot wound, XI., penetration of the knee-joint with fracture of the patella.*—The patient (1st Battalion 2nd Gurkhas) was wounded on the Samana on Sept. 11th, 1897, by a spherical bullet, which entered on the outer border of the left patella a little below the centre of the bone, fractured it, and lodged in the knee-joint. On admission here (Jan. 21st, 1898) he had a linear scar on either side of the patella. These were the scars of incisions made at Kohat in September, 1897, for the extraction of the bullet and drainage of the joint. His leg was on a posterior splint and there was marked stiffness of the joint. Fibrous union of the patella had taken place. On Feb. 2nd there was a transverse sulcus over the patella corresponding to the depression in the line of fracture. The fragments of the patella were separated by three-quarters of an inch of fibrous tissue allowing of considerable lateral movement of the fragments. There was partial ankylosis of the knee-joint owing to fibrous adhesions. The muscles of the limb were much wasted. On the 15th the condition was the same, but as the patient refused any operative interference he was sent to his regimental depôt next day.

CASE 159. *Gunshot wound in the lower extremity, IX., 1.*—The patient (1st Battalion 3rd Gurkhas) was wounded in Tirah by a spherical bullet on Dec. 8th, 1897. It entered the outer side of his left leg 3 in. below the knee-joint and emerged 2 in. behind this point. On his transfer here (Dec. 21st) the wound of exit was closed and that of entrance was nearly healed. Three days later he was sent to his depôt.

CASE 185. *Gunshot wound, XI., penetrating ankle-joint, with fracture of the fibula, astragalus, and os calcis.*—The patient (1st Battalion 2nd Gurkhas) was wounded at Dargai on Oct. 20th, 1897, by a spherical bullet which struck him over the external malleolus, smashing it and opening the ankle-joint. It passed downwards and outwards, splitting the astragalus and os calcis, and lodged about the insertion of the tendo Achillis, whence it was extracted soon afterwards. At the same operation pieces of bone were removed through the wound of entrance. Later other pieces came away through both wounds. At Kohat an abscess formed over a sequestrum close to the incision wound which was made for the extraction of the bullet. This was opened and the dead bone was removed. On admission here (Jan. 27th, 1898) he had a depressed scar adherent to the outer malleolus and the latter was much thickened. There was another depressed and adherent scar over the os calcis and a linear incision where the abscess had been opened. There was a good deal of callus over the os calcis and the ankle-joint was enlarged and stiff. Flexion and extension were reduced to about half the normal and the patient was unable to walk. Massage and gentle passive movements were commenced. On Feb. 1st there was no pain and only a slight defect in his gait, but the patient will probably be disabled permanently as a soldier. On the 22nd he was sent on six months' sick leave.

(To be continued.)

THE INFLUENCE FOR EVIL OF THE MIDDEN-PRIVY IN THE DISSEMINATION OF TYPHOID FEVER.

BY CHARLES PORTER, M.D.R.U.I., D.P.H. CAMB.,
MEDICAL OFFICER OF HEALTH OF THE COUNTY BOROUGH OF STOCKPORT.

THE influence for evil of the midden-privy in the dissemination of typhoid fever may be exerted in several ways—e.g., by soil-pollution, air-pollution, and contamination of milk, &c., by infected particles therefrom. Dr. S. Martin and Dr. J. Robertson have recently shown that in soil fouled by leakage from these receptacles Eberth's bacillus will survive and multiply for very long periods, whereas in virgin soils it loses all signs of vitality in a comparatively short time. Again, the late Sir George Buchanan truly said in 1888 in an official Local Government Board Memorandum: "In enteric fever the evacuations should be regarded as capable of communicating an infectious quality to any night-soil with which

Digitized by Google

they are mingled in privies," and Sir Richard Thorne, his successor, has recently remarked that the midden-privy provides almost every factor "favourable to the setting up and maintenance of those very conditions which seem to be essential to the vitality and multiplication of the typhoid bacilus." The value of these warnings has, moreover been established beyond all question by Professor Delépine, who in a characteristically ingenious manner demonstrated the presence of swarms of Eberth's bacillus in the detritus from between the floor bricks of a privy-pit into which typhoid dejecta had thirteen months before been thrown, the receptacle having been repeatedly subjected to careful disinfecting processes in the interval. To this striking bacteriological proof may be added an abundance of the "evidence of experience" of midden-privy towns in regard to typhoid fever.

In the appended table are set forth the statistics for Stockport during the five years 1893–97. In order to make the inquiry as equitable as possible the privy-pit houses and water-closet houses have, with much labour, been enumerated and classified from the rate-books, and the incidence of typhoid fever on each class compared *according to rateable value*, which has been taken, partly at the suggestion of Professor Delépine, as a fair indication of the sanitary condition in other respects of the two classes of dwellings.

Table showing for the Five Years 1893–97 the Incidence of Typhoid Fever in Stockport on Privy-pit Houses and Water-closet Houses respectively.

Rateable value.	Privy-pit houses.		Water-closet houses.		Typhoid fever incidence per centum of	
	Average number.	Cases of typhoid fever notified.	Average number.	Cases of typhoid fever notified.	Privy-pit houses.	Water-closet houses.
Under £5	2,811	54	176	1	1·92	0·56
£5 and under £8...	7,771	275	703	3	3·53	0·42
£8 and under £10	1,415	57	746	9	4·02	1·20
£10 and under £12	1,077	42	425	8	3·89	1·88
£12 and under £14	449	16	225	4	3·56	1·77
£14 and under £20	656	30	613	8	4·57	1·30
£20 and under £30	249	13	374	2	5·22	0·53
£30 and upwards...	147	8	369	9*	5·44	2·43*
—	14,575	495	3631	44*	3·39	1·21*

This figure does not include 2 cases reported from the infirmary and 4 from the workhouse hospital.

In 72 instances during the five years infection of a privy-pit with typhoid discharges was followed by one or more cases amongst those who subsequently used the privies. The entire number of such subsequent cases was 116 out of a total of 545 notified, or 21·3 per cent., and as many as 4, 5, 7, and 8 cases were upon occasion traced to the same privy-pit. The details are as follows. In 53 instances 1 subsequent case occurred—viz., in 37 cases within a few weeks, in 10 cases about one year later, in 3 cases about two years later, in 1 case about three years later, and in 2 cases about four years later. In 10 instances 2 subsequent cases occurred—viz., in 7 cases within a few weeks, in 1 case about one year later, and in 2 cases about two years later. In 2 instances 3 subsequent cases occurred—viz., in 1 case within a few weeks and in 1 case about a year later. In 2 instances 4 subsequent cases occurred—viz., 1 within a few weeks and 1 about three years later. In 3 instances 5 subsequent cases occurred—viz., 2 were within a few weeks and the other four years later. In 1 instance 7, and in another 8, subsequent cases occurred within a few weeks. During the same period only 1 subsequent case (and that was three years later) occurred where a water-closet was used. This was in a very large public institution, and it is doubtful whether the water-closet infected by the first sufferer was used by the second.

It is noteworthy that the figures for Stockport show that the incidence of typhoid fever increases with rateable value both in privy-pit and water-closet houses.

Stockport.

A CASE OF

CHRONIC CONSTIPATION ENDING FATALLY AND ASSOCIATED WITH ENORMOUS DILATATION OF THE SIGMOID FLEXURE.

BY PEVERELL S. HICHENS, M.A., M.B., B.CH. OXON., M.R.C.S. ENG., L.R.C.P. LOND.,

ASSISTANT RESIDENT MEDICAL OFFICER TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

THE patient was a young man, aged twenty years. The account of the case is necessarily rather imperfect, as he was not a patient of any of the physicians at the hospital, but was treated by his own medical man outside. The history of the case showed that from the day of his birth to the day of his death the patient suffered from constipation and his bowels were apparently never opened without recourse to artificial means. For the first week of his life he was exceedingly ill, passed nothing but blood and water by the rectum, and was not expected to live. After the first week he began passing fæcal matter, but the motions were never those proper to an infant, consisting almost entirely of scybala, and they were passed with much pain and screaming. The motions, such as they were, were not obtained without previous ½ oz. doses of castor oil, which often had to be repeated two or three times in the course of twelve hours before the bowels acted. As the child grew the bowels were only opened by drugs, and with increased difficulty, and at the age of twelve months the mother began to have recourse to ½ pint enemas of soap and water. Later enemas of a whole pint had to be given and very often had to be repeated two or three times before the bowels were opened. The after-history of the case is merely a repetition. The bowels used only to be opened at intervals of ten days or a fortnight and only after repeated enemas. A very large scybalous motion was then passed, generally succeeded by several loose motions, spread over the next two or three days. The motions could only be passed by the help of gravity—i.e., squatting down over a chamber in the position which, as Dr. Lauder Brunton has pointed out, is the natural and proper one for defecation. The patient very often felt slightly sick before the bowels were opened and was very much collapsed afterwards, so much so that he often had to go to bed for the rest of the day. His abdomen was always greatly distended, so that he could never button the bottom button of his waistcoat or the top button of his trousers. About a month before he died he was taken ill with influenza and on getting better he went away into the country for a holiday. Five days before death he was seized with pains all over his body and slight swelling of the legs, and in consequence he hurried home. He was treated by a medical man who thought that he had a slight touch of rheumatic fever. The night before he died he passed a fairly large motion. On the morning of the next day he was seized with a severe pain over the heart for which the præcordial area was rubbed with liniment, which gave him considerable relief, and shortly afterwards he went to bed feeling fairly comfortable. During the following night he suddenly got out of bed for some unknown reason and fell down dead.

The body was brought to the hospital, and at the necropsy it was found that it was well developed and that rigor mortis was not present. There was very slight œdema over the feet and shins, but enormous general distension of the abdomen. On reflecting the parietes the abdominal cavity was found to be occupied by a tense shining viscus, presenting the appearance of a sac rising out of the pelvis and passing under the ribs, where it doubled on itself and returned to the pelvis again. On closer inspection this proved to be an enormously distended sigmoid flexure. At the point where the sigmoid flexure left the descending colon it turned on itself and passed directly up the left side of the abdomen. The summit of the viscus then passed behind the ribs and xiphisternum with a gentle curvature and descended along the right side of the abdomen to the pelvis to join the rectum. Some little distance above the junction with the rectum the viscus showed a distinct constriction. The remaining abdominal viscera were entirely concealed by the sigmoid flexure, which pushed the liver upwards and backwards, compressed the lungs, and rotated

the heart upwards and outwards. On removing the sigmoid flexure and laying it open it was found to contain an enormous amount of gas and also a large quantity of semi-liquid fæces of the consistence of pea-soup. The total length of the sigmoid flexure when it was opened and laid flat was 22½ inches. Fourteen inches from its upper end was a large cicatrix formed by an almost healed ulcer, probably stercoral in origin, which had caused the constriction above mentioned. The circumference of the flexure above the ulcer was 14 inches, at the ulcer it was 7¾ inches, and below the ulcer it was 10 inches. These measurements, of course, represent the circumference of the flexure at its period of least distension, and they also show that the constriction at the site of the ulcer was merely a relative one and could have made no difference, or very little, to the onward passage of the fæces. The walls of the sigmoid flexure were uniformly greatly thickened. This thickening was shown on microscopical examination to be almost entirely due to great hypertrophy of the circular and longitudinal muscular fibres. There was also slight thickening of the submucosa. As regards the rest of the organs, the pharynx, œsophagus, and stomach were quite healthy. The small intestine also showed no lesion and was not at all distended. There was slight general distension of the cæcum and of the ascending, the transverse, and the descending colon. This distension was not at all marked and the large intestine appeared otherwise healthy, as did also the rectum, and there was no sign of a fibrous band, kink, or constriction anywhere except at the ulcer above mentioned. The lungs were small and compressed by the abdominal distension and were slightly œdematous and engorged. The heart was somewhat displaced but was otherwise perfectly sound, as also were the liver and spleen. The cortices of the kidneys were slightly swollen and streaky and on microscopical examination the renal epithelium appeared to be in a state of cloudy swelling.

The disease in this case would appear to come under the heading of so-called "idiopathic dilatation of the colon." Dr. Hale White, in his excellent article on the subject in Allbutt's System of Medicine,[1] mentions that only 12 cases have been recorded in the last forty years, and he provisionally groups them under two heads—those occurring in elderly patients and those occurring in young children due to some congenital inertness of the bowels. Whatever may be the initial cause—whether it was due to a temporary kink, as Rolleston and Haward[2] suggest, or to the length of the sigmoid in children readily allowing kinking, as Jacobi[3] suggests, or to mere constipation and distension with wind or local spasm of the rectum, as Gee[4] suggests, the attempted remedies in this case must probably have increased the disease. The patient moved in a vicious circle and the sigmoid, already distended, was ever being more distended by the successive enemas administered. So far as could be judged from the post-mortem appearances the only possible treatment which could have had any permanent success would have been a lumbar colotomy.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON PTOMAINE POISONING.

BY JOHN CAHILL, M.D. DURH., F.R.C.S. ENG.

THE subjoined instance of multiple poisoning by apparently wholesome food has occurred under my direct observation and may be considered worthy of record.

On Oct. 13th a brace of wild ducks, which appeared to be in very good condition both before and after cooking, formed part of the dinner of a party of five. All five persons partook of the ducks without any ill effect. On the 14th a portion of wild duck, cooked the day before, was eaten at dinner by two persons, appeared very palatable, and produced no ill effect. On the 15th the bones of the same ducks were placed by the cook in her stock-pot together with the meat for soup. At dinner on that evening there were three persons, of whom one took no soup, one took soup only, and the third took the soup and other courses of the dinner which followed it. Within less than half an hour the two persons who had taken soup at table were seized with sickness and continued to vomit violently for about twenty minutes. The person who had partaken of the rest of the dinner, but not of the soup, was not in any way affected. The cook had tasted the soup by drinking about half a teacupful before it went up to table, and she was seized with sickness and vomiting after about the same interval and in the same manner as the two persons upstairs. The soup was obviously the cause of the sickness in these three cases, and there was the following evidence to show that the poisonous element in the soup proceeded from the wild duck, although these had been eaten without harmful result on the two preceding days and had appeared to be perfectly sweet when used as an addition to the soup. When the cook had sent the soup up to table it happened that she gave a bone of duck out of the pot to the cat. A little later, when the three cases of sudden sickness had occurred, inquiry was made as to the effect of this food upon the cat. That animal was found at the back of the house vomiting and evidently in great distress. None of the sufferers appeared the next morning to be any the worse for their experience.
